At those forges where heavy work is done, a swage-block should be provided. This should be placed at the right hand side of the anvil, and 5 feet from and in line with the anvil, that is, the same distance, 10 feet from the wall. Also, over the heavy forges, a swinging jib-crane should be installed. Its jib, fitted with a runner carrying a pair of chain blocks should be sufficiently long to command the anvil and swage-block and sufficiently high to clear the swinging of a sledge. The best position for the cooling trough, or "bosh," as it is sometimes called, is immediately in front of the forge, so that it is close to the blacksmith's right hand, as he stands at the fire.

Immediately to the right of the anvil a small stand should be situated, on which the blacksmith can place such tools as he requires for immediate use, and under this stand, sunk in the floor, a small cooling trough should be placed, in order that the edges of setts and gauges may be quickly cooled when cutting large pieces on the anvil.

Directly at the back of the anvil, on the side away from the smith, a heavy cast iron block should be sunk in the floor; on this block work of medium length may be upset or "jumped." A tool bench should be placed against the wall, on which the top and bottom anvil tools, swages, fullers, etc., may be kept, and fixed to the wall on either side of the tool bench should be racks for the tongs.

At the side of the blacksmith and directly at the back of the next forge,

a bin to hold a supply of fuel should be placed.

The plan, Fig. 1, clearly shows the position of the various items of the equipment.

Not the least important part of the blacksmith's shop is its floor, and opinions vary very much as to what is the best material to use. The writer has found nothing better than brick-earth or clay mixed with ashes, in the proportion of 3 of earth to 2 of ashes. This, if watered once or twice a day, sets most firmly and makes an ideal working stand.

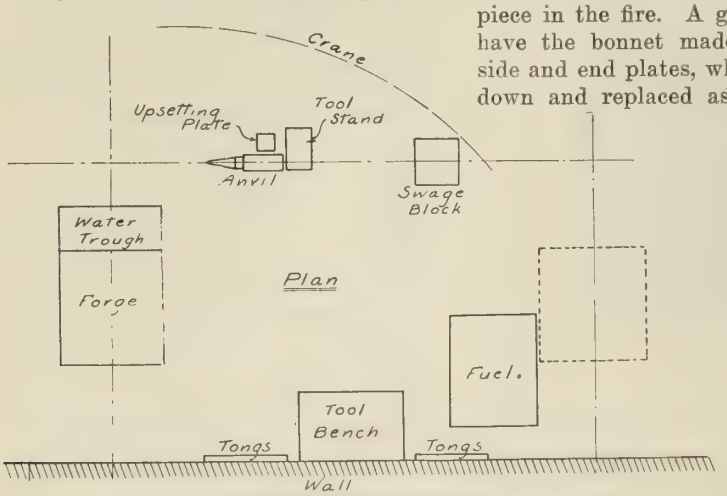

Fig. 1—Equipment Lay-out.

Having described the general arrangement of the forge I will now proceed to discuss each item and the various tools in detail. There are, however, numerous tools and other apparatus in the general equipment which are used occasionally only; these I propose to describe later.

The Forge.

The forge or hearth may be constructed of a variety of materials, cast or wrought iron, stone, brick, or even concrete. It matters little which, as long as the means of obtaining and maintaining the required heat are satisfactory, and that there is an efficient bonnet and chimney-stack to carry off the smoke and gas. The size best adapted for general work is 45 in. square, with height of 30 in. The blast should be introduced through the breast wall by means of a water jacketted tuyere. This should project into the hearth 9 in. and be at a depth of 6 in. below the level of the hearth plate. The bottom of the forge should be at least 6 in. below the tuyere, in order that dust and clinkers may collect without choking the blast. The orifice of the tuyere should be 1⅜ in. diameter, and the supply pipe leading from the blast trunk 3½ in. diameter. A windgate or shutter must be placed in the supply pipe, directly behind the breast wall. This is actuated by a lever placed close to the blacksmith's left hand. The tank for supplying water to the tuyere jacket must also be at the back of the breast and placed about 1 foot above the centre of the tuyere. The chimney stack must be not less than 10 in. diameter, and be carried far enough through the roof to insure a good up-draft. It should be kept well back and the bonnet made as narrow as possible, in order to clear the crane blocks when working a heavy piece in the fire. A good practice is to have the bonnet made with removable side and end plates, which may be taken down and replaced as required.

The Anvil.

The anvil for general machine blacksmithing should be of the standard pattern, of wrought iron with a steel face, and its weight from 300 to 350 lbs. Where several anvils of the same weight and pattern are used, care should be taken that the square hole for the tool shank is straight and of the same size in each, so that tools made for either anvil may be used in the others without danger of jamming and breaking the shanks.

The anvil may be mounted on a wooden block, but by far the best practice is to mount it on a hollow cast iron base, as shown in Fig. 2. It will be seen that the weight is carried by a substantial flange. Inside the base and 3 inches from the top edge, fitting snugly on this flange, a hardwood block 2 inches thick should be placed, forming a cushion for the anvil to rest on. The back and front top edges of the base are cut away as shown, in order that the scale may find its way onto the floor and not work under the anvil. In setting the anvil the back edge should be kept about ⅛-in. lower than the front, that is, the face should incline from the smith by that amount. This makes the work much easier to handle. Care should be taken when working, not to leave large heats on the anvil longer than absolutely necessary, as this has a tendency to draw the temper and soften the face.

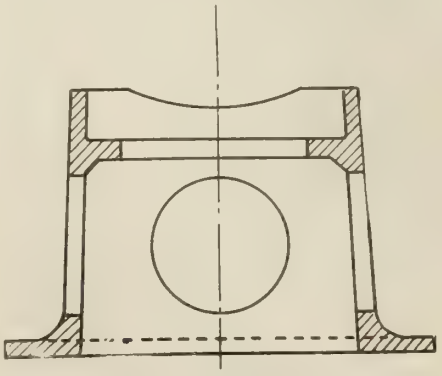

Fig. 2—Anvil Stand.

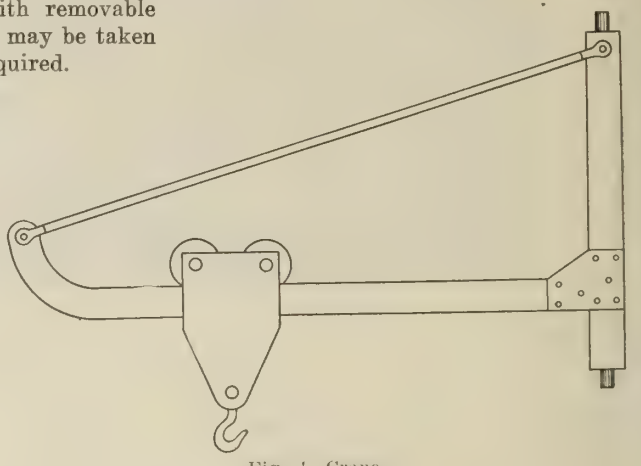

Fig. 4—Crane.

The Swage Block.

The swage block is an extremely useful tool; the best type for general work being the rectangular one, having its edges indented for swaging square, round and hexagon work, and its centre pierced by square and round holes for heading. One side of these holes should be countersunk. It should be supported on a cast iron base as shown in Fig. 3, so that it may be securely held on its edge for swaging or on its flat for heading. The swage block is also very handy to use as a bolster for punching and drifting collars and washers.

Cooling Troughs—Tool Stands—Upsetting Plates.

The cooling troughs may be either cast or wrought iron, the larger one at the forge 42 in. long, 18 in. wide and 21 in. deep, and the smaller one at the anvil 12 in. square and 12 in. deep; the latter being sunk in the floor for a depth of 7 or 8 inches. The tool stand at the anvil should be a plain wrought iron or wooden stool 15 in. wide by 18 in. long, and its height about 3 in. less than that of the anvil. It should be so placed that its legs straddle the small cooling bosh without interfering with access to the water.

The upsetting plate should be a plain rectangular block of cast iron, 12 in. square by 5 in. thick, sunk level with the floor.

Tool Bench—Tong Racks.

The tool bench should be substantially built of wood, 42 in. long by 28 in.

wide and 36 in. high, fitted with a drawer in which the smith may keep his private tools, drawings, etc., and a shelf underneath about 1 foot from the floor. At the back and ends, rails should be fited to carry top tools; that is, those with handles. The lighter bottom or shank tools may be kept on the top and the heavier ones on the shelf underneath. Tools should be put away immediately they are done with, and if every tool is kept in its place, much

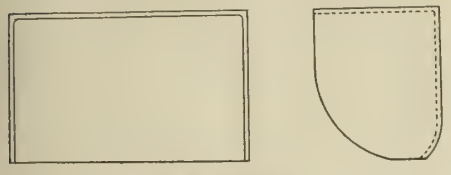

Fig. 5—Fuel Bin.

valuable time will be saved when they are wanted.

The tong racks are very simply made; a piece of 1 in. round stock with the ends bent at right angles and plugged securely into the wall, about 30 inches from the floor and standing out 3 in. from the wall, answering every purpose. The tongs may be hung over this bar, reins downward.

The jib crane can be very cheaply constructed. Fig. 4 shows the most suitable style and is self-explanatory. The runner shown carries a light set of differential chain blocks, and a small snatch block must be hung on the bottom block hook, with a short endless chain passed through it. The work is carried in this endless chain and can, therefore, be raised, lowered or turned in any direction required. When the crane is not in use it can be swung out of the way and the blocks run back against the wall. This crane will be found much more convenient than trestles or horses for supporting heavy work; being easily adjusted and always at hand when wanted.

Fig. 5 shows a suitable type of fuel bin. This should be 45 in. long, 36 in. wide, 30 in. high and may be made of either cast or wrought iron.

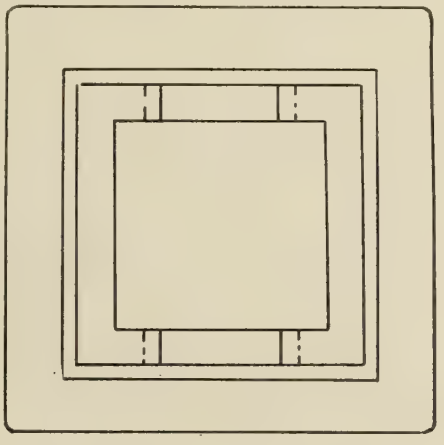
Working Tools—Hammers.

The blacksmith's working tools comprise hammers, top and bottom anvil tools, flatters, set hammers, hot and cold setts or chisels, gouges, punches and tongs. Each forge should have five hammers, as follows: The smith's hand hammer or "pointer," of standard ball-peened shape, 1¾ lbs. weight, fixed on a handle 20 in. long, and the "back" hammer, a small double-faced hammer, 4 lbs. weight, with a handle 24 in. long. This hammer should always be kept directly back of the anvil, being found extremely useful for swaging small work to a nice finish or other light jobs. Three striking hammers or sledges are required; one of 8 lbs. and one of 12 lbs. weight for light and medium work, and one of 16 lbs. weight for setting, straightening and heavy striking.

These hammers should be of the cross-peened type, as they are better adapted to working the edges of a scarf when welding. The smith and his helper should pay close attention to the fitting of the hammer handles, as many serious accidents have been caused by hammer heads coming loose and flying off.

Working Tools—Swages, etc.

The top and bottom anvil tools, for general machine work, comprise a great variety of shapes, the most common of which are swages and fullers. These should always be made in pairs and accurately matched, and attention given to the following points. Swages must be made so that the depth of the impression is 1-3 the diameter of the work to be finished, and the edges of the ends and sides of the impression must be well rounded off to prevent marking or cutting the work. It is also important that the impression be slightly crowned from end to end. The shank of the bottom swage should not be situated in the centre, but at one end, so that when the swage is placed in the anvil, one end comes flush with the edge. This will enable work to be swaged close up to collars or arms. The swage can also be reversed and used



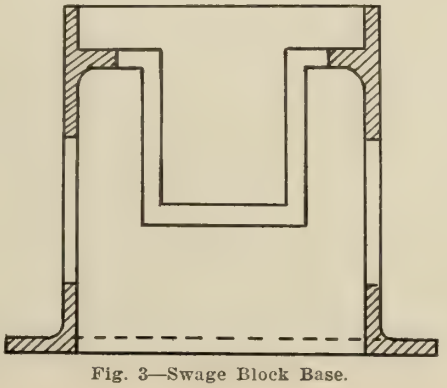


Fig. 3—Swage Block Base.

from the other side of the anvil. The bottom swage should bear fairly on the anvil and the shank must not fit too loosely in the hole. The top swage must be made from ½ to 1 in. shorter than the bottom according to size; the correct length for the bottom part of

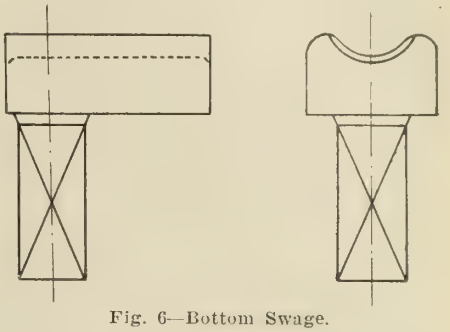

Fig. 6—Bottom Swage.

a 1 in. swage being 3½ in. and of the top part 2¾ in. Fig. 6 shows the correct form of a bottom swage. Care must be taken when forging the top tools not to make the head too light around the eye, as it is here that they most frequently break.

Fullers are not so important as swages, having no sharp edges to come in contact with the work. They should be made accurately in pairs; the bottom part having a wide and sufficient bearing on the anvil and the shank fitting nicely in the hole.

Flatters and set hammers should not be made too large; a good size for the flatter being 2½ in. square, with corners slightly rounded and centre crowned 1-32 in. This gives much better results than a dead flat tool 3 in. square. Three set hammers are necessary for general work; two of these should have faces 2¼ in. long by ¾ in. wide and one a face 1⅜ in. square. In the longer ones, the length of the face of one should run parallel to the eye and in the other it should run at right angles to it. Again, the long corners of both should be rounded off to a radius of 3-16 in. The square set hammer should have its corners but slightly rounded as in the flatter. Sets, gouges and punches must be made to suit the work as required.

Tool Material and Temper.

Swages, fullers, flatters and punches should be made of steel, having a carbon content of .60; sets and other cutting tools of .75 carbon steel.

It will be found that tools such as swages and flatters will give better satisfaction and last far longer if they are tempered both on the heads and faces. When hardening the face of a swage or flatter, it should be quenched under a water tap or faucet; allowing the stream to flow directly on the centre of the face until cold. The temper should then be drawn till the centre comes to a brown and the edges a blue

temper color. The head should next be hardened and the temper afterwards let down to a dark blue. Tool heads tempered like this will stand much hard work without cracking or bruising.

Working Tools—Tongs.

Tongs form a very important part of blacksmiths' tools. If he does not have tongs which will hold his work firmly, it is impossible for him to do a good job. There are several varieties of tongs, each adapted for a special purpose and each having a distinctive name. Those made to hold flat bar stock are called "flat bitts," those for holding round stock "hollow bitts." A pair of flat bitt tongs made to hold very thin stock are sometimes called "close bitts." Flat bitts made to hold large stock have lips on one jaw which grip the sides of the bar and prevent it moving sideways; these are called "box bitts." Tongs made for holding headed work, such as locomotive drawbar pins, are bowed outwards between the jaw and the joint, these are called "goose neck" tongs. There are also special tongs used for holding deep collars while being swaged on the beckhorn; these are flat bitt tongs with the jaws bent downwards at right angles and are known as "duck bitts." A pair of tongs very useful at the forge are the "dandies" or "pliers." These have very long narrow jaws, meeting close at the points and having two or more goose necks or corrugations in the jaws between the nose and the joint. They are used to pick up small objects which are too hot for the bare hand—bits of scrap, drifts, devils, etc. They should always be kept at the back of the anvil with the "back" hammer, as they are essentially a helper's tool.

Care must be taken in making tongs that they are well proportioned to the size of the stock they are intended to hold. The joint should be forged without any sharp entering corners and free from "cold shutts." The jaws or "bitts" should taper from the nose to the joint, and the handles or "reins" from the joint to the tips. In making tongs, it is much better to forge the rein in one piece with the bitt than to forge the bitt separately and then weld on the rein. Flat bitts should have a small V-shaped impression running the length of the bitts; they can then be used for holding small square or round stock. Hollow bitts should be made with V-shaped bitts in preference to circular ones; they will grip round stock better and can also be used for square bars.

Flat Bitt Proportions.

The following are the correct proportions for a pair of flat bitts to hold 1 in. stock: Diameter of joint, 1¼ in.; thickness of bitt at joint, ¾ in.; thickness of bitt at nose, ½ in.; width of bitt, 1⅛ in.; depth of V, 3-16 in.; length of bitt from centre of joint, 3¼ in.; length of rein from centre of joint, 22 in.; depth of rein at joint, ⅞ in.; width of rein at joint, 9-16 in.; diameter of rein at tip, ½ in.; diameter of joint rivet, 1½ in.

In order to hold the tongs firmly onto the work, the ends of the reins should be pressed firmly together with the hands and a small link, or "coupling" as it is sometimes called, should be then passed over the tips and pressed up toward the joint; this binds the reins closely together and, of course, tightens the grip of the tips in proportion.

BUSINESS IDEALS.

BUSINESS ideals must be considered as influencing factors in the work of the world. These ideals are as wide as they are varied. Money-gathering is one (it is of the common or garden variety); contributing to the work of the world's industrial development is another; materially aiding one's fellowman is a third, and—well, there are many others! What is yours? Ask yourself and answer honestly. Will the reward compensate you? If you feel that, even should you chance to be successful at the present time, or if your success is still to come—if you feel that the reward is, or will be unsatisfactory, then your business ideal is wrong—and you had better change it. Are you seeking comfort and ease, a cessation of active work? Don't do that! To stop work as long as you are able to continue your task is a grave mistake. Are you aiming to achieve success, so that it will enable you to benefit others? That's better, for it gives you a business ideal that is worth while. How many are included by the way, among those others? Are there only a few of those near and dear to you? Then widen the circle, for there are many—many, indeed, staggering by the wayside, weak from the want of encouragement, rather than from want of food—thirsty for help—but for help of the right kind. There are very few, indeed, who want charity—if they can get what they want in the right way. Give it to them in the right way. Don't pauperize, but "father them." Don't preach, but practice. Many of the things you can buy with money are valueless. Vice versa many of greatest value are not purchasable with all the wealth of Christendom—yet some of them can be obtained for the mere taking—if you are entitled to them—or if Life feels that you should be rewarded by them.

Certainly the street car is uncomfortably crowded, but does that give you an excuse for scowling at some poor and equally tired fellow-traveller who, hastening home to those who may be waiting for him, has reduced the amount of your standing room by one-half, because he must get on board to save five minutes that may be more precious to him than to you! Is your fellow worker uncivil? Bear with him. The high cost of living may have affected him more than it does you! Perhaps a word from you will help. Why do you withhold it? Bring in some business ideals! Civility is a good one—set the example.

Is he worrying you for that check to settle the account you owe him? Wait a moment—perhaps somebody is worrying him for money—just as you are worrying some one else. Help him if you can by paying promptly. If you can't, tell him so, and explain honestly that "collections are slow" and prove it to him if you can do so without a breach of business confidence and ethics. Did that telephone girl get the wrong number? "Stupid!" you say; but did you ever visit "Central" and see the strain to which she is subjected? Do you think you could do the work and not make a single mistake? By the way do you ever make a mistake? Don't swear at her—fortunately the telephone company won't let you repeat the offence—don't swear, but wait a moment, with a little patience. A succeeding second may find you closing that deal with the party you want.

Business ideals! They can be applied to each and every phase of life—if you know how to apply them. If you don't know how, try and learn. It's worth the effort. Busines ideals! They mean not alone success, but happiness as well.—Nat. Commercial.

DOMINION IRON AND STEEL CO.

Mr. Arthur P. Scott has been appointed superintendent in charge of the steel department of the Dominion Iron & Steel Co., at Sydney, C.B. Mr. Scott entered upon his duties on March 31. The new superintendent has been connected with the Steel Co. for a number of years; having held the position of chief chemist until 1908, when he resigned and went to the Alleghany Steel Co. He returned last November to undertake the supervision of the metallurgical department. Mr. Scott is a son of Rev. Dr. Scott, of Montreal, editor of the Presbyterian Record, and a native of Nova Scotia.

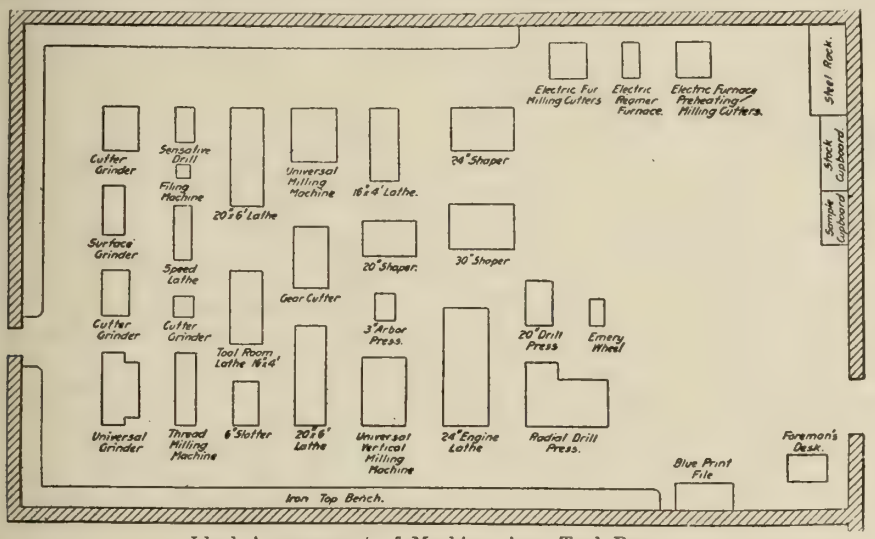
The new general office building of the Steel Co. at Sydney is about completed, and the departments which have been located in office buildings in various parts of the city are being moved there. The offices are said to be among the finest on the continent.

RAILWAY TOOL ROOM EQUIPMENT.

By B. Henrikson.

THE question of the proper equipment for a railway tool room is determined by the special conditions of every railway shop. The number of engines to be repaired, the kind of tools and the extent of work done are factors to be considered in equipping a tool room. The ideal tool room should be so located, so equipped, so organized and so managed as to give the quickest and best repairs to broken shop tools, and the most efficient work in the manufacture of new tools, dies and special machine parts.

The tool room of a large locomotive repair shop has two functions: (1) the distribution and proper care of small tools for the daily use of shop men; (2) the repair of machine parts, special tools such as pneumatic motors, hammers, etc., the manufacture of dies and new and special tools.



Ideal Arrangement of Machines in a Tool Room.

The proper location of the distribution room is in the centre of the main shop, at a point convenient to both machine and erecting shops. The size of this room is determined by the number of tools required for the monthly engine output. The tool racks are so arranged as to give the greatest accessibility to tools; pigeon holes and pockets are plainly indexed and of such number as to accommodate every tool. An iron covered counter circumscribes the racks and is protected on the outside by a high steel grating. Openings of ample size for handling shop tools are provided in the gratings at points opposite tools receiving the greatest use. For instance, there is a window opposite taps, drills and reamers; another opposite dies, wrenches, etc.; another opposite air motors and the heavier tools. Such an arrangement greatly facilitates the quick handling.

The stock of taps, drills, reamers, etc., should be of such size that the breaking of a few of the same dimension does not necessitate the holding up of shop work. These damaged tools should be repaired at once and placed in their proper rack. In the average size shop there is work enough in the grinding of small tools to require continuous attention of one man and the employment of such a man is economy. The distribution room should be equipped with a twist drill grinder, a reamer grinder, an efficient grinder for lathe and planer tools, and a grinder with two 12-inch wheels for general work.

The second function of the tool room, the repair of machine parts and the manufacture of new tools, dies, etc., is of such importance as to require an especially equipped room. This room should be located away from the noises of the erecting and machine shops in a building annexed to the machine shop. This location prevents night men from trespassing in the search of tools, and the consequent misplacing of important work. It also provides a quiet place for the careful and painstaking labor of die and tool makers. The room should be constructed to give a maximum amount of light and air. The roof lighting system with prismatic glass windows facing the north is an excellent lighting method, and together with wall windows make the tool room especially well lighted.

Machine Arrangement.

The machine arrangement in the ideal tool room is shown in the accompanying sketch and consist of the following tools:

1—24-inch lathe.
2—20-inch lathes.
2—16-inch special tool room lathes equipped with taper attachments.
1—Speed lathe, 12-inch swing, 5-inch bed.
1—Milling machine.
1—Universal gear cutting machine capable of cutting spiral and bevel gears.
1—48-inch Radial drill press.
1—20-inch power feed drill press.
1—Sensitive drill for work up to ½ inch.
1—Vertical milling machine.
1—Tap milling machine with automatic cutter grinders.
1—42-inch Universal grinding machine.
1—Universal cutter grinder.
1—Grinder for two wheels 16 inches diameter.
1—Up-to-date filing machine.
1—6-inch slotter for die work.
1—30-inch shaper.
1—24-inch shaper.
1—20-inch shaper.
1—Cutting-off saw for cutting up stock.
1—Electric centre grinder.
1—Portable floor jib crane to handle heavy work at machines.
1—3-inch Arbor press.
1—Electric furnace for hardening high speed reamers.
1—Electric furnace for hardening high speed milling cutters.
1—Electric furnace for pre-heating high speed milling cutters.
1—Full set B. & S. plug and collar gauges.
1—24-inch steel gear rule.
1—96-inch B. & S. standard steel rule.
1—12-inch Vernier calipers.
1—24-inch hardened cast steel try square.

In the grouping of tools it has been found that where grinders have been placed near lathes and other machines having exposed wearing surfaces, that the emery dust has caused increased wear on these parts. It is well to separate machines that have such surfaces or apply suction fans to emery wheels and remove the flying emery.

The machine tools should all be individually motor driven. This system eliminates the cumbersome shafts and belts and unnecessary wear when the machines are not in operation. It prevents the possible "tying up" of the whole tool room when a main belt breaks, and eliminates the necessity of running the whole shop when the use of only one machine is desired. The direct motor drive allows an absolute independent location of every machine, which is impractical in the belt driven shop where the best belt arrangement often determines the location of tools.

Benches with iron tops, drawers and locks should be provided for the men; and swivel jaw vises should be placed at convenient places on the benches. Cupboards for sample work, and for filing of blueprints should be provided at convenient places. The ideal tool room is provided with a suitable rack for a

light stock of annealed tool steel. Pin racks placed on the walls for milling cutters and emery wheels are very necessary. Cupboards for the proper storing of finished tools should also be provided.

It is obvious that the quicker a broken engine is repaired, the greater is the earning capacity of a railroad. Engine repairs must be made with tools; the tools must be in good condition, ready when wanted and quickly despatched to where they are required. It follows that the tool department of the locomotive repair shop is an important factor on a railroad. This importance demands efficiency; and the tool department, separated into two distinct parts and equipped as described above will meet this demand. — Ideal Power.

PAY UP.

THE man who can pay his bills and doesn't is one of the public enemies who are responsible for the slow recovery of business. He cripples industry, restrains trade and creates a long line of debtors who cannot pay. He is a brake upon prosperity, a drag upon humanity. He has been a deterrent factor in business the past five years, ranking in depressive effect next to the financial flurry of 1907. The habit of deferring payment, contracted anew in 1907, has become chronic with individuals, firms and corporations, and has served to harass business to an extent appreciable only to the bankers who carry the accounts of the retailers and smaller manufacturers. By withholding payment of one bill a procession of difficulties is formed. A hoards his cash and embarrasses B, who has to put off C, and D is pressed to the wall. The chain of evil, started by the prosperous, reaches down through the ranks of industry, commerce and labor, cramping enterprise, confining trade and galling most of all the men at the bottom of the business structure.

This survival of panic times has become engrafted upon our business system to such an extent that in some circles the pride in being considered "prompt pay" is now regarded as old-fashioned, and skill in putting off one's obligations has come to be reckoned a desirable acquirement.

The business situation to-day, however, seriously demands the classing of the deliberate slow-payer with the cheat. His reformation would free the involuntary slow-payer from a plight that is none of his choosing, and would make the wheels of business hum with prosperity.

You who can, pay up. Then those who now can't pay will be able to do so. Money will flow faster through the arteries of the country's life, and all the people will be benefited.—N.Y. Evening Mail.

THE CRAZE FOR HIGH SPEED.

Inventive genius saves time with a spoon for people who waste time with a shovel. For every ten minutes that labor-saving machinery "economizes" in the construction of a modern building, an hour is wasted by the sightseers who stand idle on the street and watch the machinery at its labor-saving work.

The telephone is a real blessing that degenerates into the curse of unnecessary talk. The typewriter becomes an agency for the multiplication of useless letters. The theory that this generation's time is precious, and there is not a minute to waste, is one of the superstitions of a deluded people who save hours on a journey in order that they may squander days at the journey's end.

Months for pleasure, but not a minute for safety, is the motto of this speed-crazed day and generation.—To. Tm.

OCEAN WRECKS AND RAIL WRECKS.

Captain Smith, of the Titanic, cannot be blamed for the disaster that befell the Titanic any more than the engineer can be held responsible for the terrific speed at which he was compelled to run, but which broke the heavy modern rail under his train. Both acted under rigid instructions from their superiors to "smash all records."

There is one sure and certain way to escape such disasters, and that is to avoid record-breaking steamships and railroad trains. Many busy men of affairs in the middle West board the slower but safer trains when traveling, and their number is being constantly added to. When the American traveling public reaches the same conclusion that it would rather arrive safely at its destination than merely "clip off" a few minutes here and there; only to sit around and boast of it after getting there; in other words, when the traveling public prefers safety to boasting, when it has learned to use the minutes of the day for actually useful purposes rather than to boast of its sham and pretence of "rushing"; then traveling on land and sea will be far safer. There will be little heard of "faulty steel."

Rail breakages and shipwrecks have much in common. Both are sacrifices to the Moloch, speed. Both are the legitimate fruit of the modern curse: "Hurry up!!"—D. I. T. Review.

PRODUCTION AND WAGES.

I APPRECIATE the fact that there is a good deal of opposition to be met in labor unions, and that the leaders of these bodies are standing, as usual, in their own light. The effort of labor unions has always been to increase wages and curtail production, in the belief that this policy was bound to improve the condition of labor, but regardless of the fact that the wage-earners of the world are its principal consumers, and that limitation of output increases the cost of everything they buy, and multiplies the privations they have to bear.

One is reminded of Carlyle's observation on the vast numbers of human beings in this world, "mostly fools," and without doubt a campaign of education is needed to illuminate their real interests and show clearly that the greater the products of labor the greater the wealth to be divided and the greater the workman's share in it, because he always has the lion's share, notwithstanding the unequal distribution among the rank and file in the whole industrial army. An increase in wages is obviously a good thing for the wage earner, at the expense of the consumer; but when the increase in wages becomes general, the cost of living naturally rises in the same proportion, and nobody is economically any better off. When production however, increases along with wages, the cost of living is held down and labor is more prosperous. So also when more is produced for the same wages, the cost of living drops, to the manifest advantage of all labor. The real interest of labor lies, therefore, in the maximum production and the most advantageous distribution of wealth to the proletariat.

The maximum production can be brought about, however, only by unequal distribution, which supplies the necessary incentive to bring out the best effort of the individual worker in every form of active business life. The proletariat is too prone to think that he is the whole thing in the production of wealth, whereas in many lines of trade it costs more to sell than to produce, and still more in interest on the capital invested, which is just as necessary as labor itself. It cannot be denied that good wages help consumption far more than excessive profits in a few hands, and, to maintain a steady market and a good demand for all the products of industry, let us hope that capitalists and the captains of industry will eventually realize that it pays to be liberal to the lower ranks of labor, and so build up a higher type of citizenship, which will produce and consume a large portion of the good things of life. To this end scientific management is moving, and motion study, as a part of it, is helping the good work along.—Wilfred Lewis, in Engineering, Jan. 5, 1912.

Vol. VIII. MAY, 1912 No. 5

PLANT OF HARLAND & WOLFF.

IN view of the widespread interest aroused by the recent foundering of the steamship Titanic with over 1600 souls on board, we have given on pages 153-4-5 of this issue a brief illustrated description of prominent machine tool and other equipment features of the world famous shipbuilding and marine engineering plant of Harland & Wolff, Belfast, Ireland, the designers and builders of the Titanic and her sister ship, the Olympic.

THE TITANIC DISASTER.

CANADA, in common with the Motherland, the United States and other nations of the world, has been hard hit by the disaster, which overtook the magnificent and luxuriously appointed White Star Line steamship Titanic in mid-Atlantic on the early morning of April 15. Men prominent in various fields of enterprise in this Dominion, met what we might be disposed to claim an untimely end, yet, on reflection, it surely may not have been so, else that heroism which they displayed would have been shorn of its sublime naturalness and grace.

Not only is a world of sympathy being tendered the bereaved relatives of all who went calmly down to death, but, in addition, there is already being prepared the foundations for that undying monument to brave men and women, which will make our means of transportation not merely conveyances of more or less luxury, but at the same time veritable Museums of Safety. The big ship was never claimed by responsible people to be unsinkable, but we are afraid that the eye, the appetite and the long purse were more prominent in the catering arrangements than was the provision for the conservation of human life. A few months ago, we directed attention in these columns to the efforts being put forth, concerning this latter feature in large manufacturing industries throughout the civilized world, and while, as a result of this tragedy, we look for the greatest developments in the conservation of life and property taking place in matters marine, there will undoubtedly also be given considerable impetus to the propagation of a like result on land.

SYSTEMS OF SHOP MANAGEMENT.

RECENTLY the special committee of the U.S. House of Representatives appointed to investigate the "Taylor and other systems of shop management," submitted its report at Washington. Included within the scope of the work, the committee was empowered and expected to determine the applicability of any or all of the "systems" to Government shops, their effect on the health and pay of the employes and such other points as might be noted as the result of the installation and operation of a particular scheme. While attention was directed to different systems which were found installed in a more or less limited number of manufacturing establishments, particular attention was directed to that known as the "Taylor system," because of the fact that it had already been introduced into a few Government plants and was under consideration for others.

The net result of the committee's investigation is that, while a large amount of good has been accomplished in working out the details of "scientific methods of shop management," neither Mr. Taylor nor anyone else has presented a system so complete and perfect as to justify a recommendation that it be imposed in its entirety in any Government shop.

The report is remarkable for its thoroughness of insight into the economics of the various questions and contingencies involved, and bristles with plain, simple, blunt, unvarnished statements of considerations to be accounted. It is clearly indicated that the employe be recognized as a man and that he be treated as such. It is also made impressive that the introduction of any efficiency scheme, be one of evolution instead of revolution, and that mutual conference and consent, the parents of beneficial results, are at all times preferable to the imposition of "efficiency" ideas on an unprepared and, therefore, naturally unwilling working force. Efficiency may not be practised at the cost of men, women and children who labor; rather should they be the prime beneficaries.

The report recognizes the distinction between a man and a machine; the latter having neither life, brain, sentiment or place in our social order, and in this reference says, that "he would be less than a man did he not resent the introduction of any system which deals with him in the same way as a beast of burden or an inanimate machine."

We have only referred to those features in the report around which more or less discussion has raged; believing that a due appreciation of the importance of these as set forth in this committee's able and timely report, will accelerate, more than anything has yet done, an unsuspicious acquiescence on the part of those who serve, and a reasonable considerateness on the part of those who direct.

Even if it accomplishes nothing else, it should effectually quench the "efficiency engineer fever" and stop the penning of the more or less brainless effusions which have appeared from time to time by people who could not do a day's work without leaning on somebody else or helping themselves from what somebody else already owns.

Factory Lighting

THE need for an improved artificial lighting in factories and workshops has previously been emphasized in our columns. It would seem likely that factory owners will be forced by legislation to improve existing means and methods of lighting their workshops. That the direct physiological effect of good lighting is an improvement in the quality and quantity of the output of the various operatives is fairly obvious, but there is another very serious aspect of the case which factory owners would do well to consider. Inefficiency and insufficient lighting is the cause of a large number of accidents; this being borne out in statistics published by Government departments, and further substantiated by the opinions of Insurance companies. In fact one large company places poor lighting first amongst the general causes of accidents.

It is not a very difficult matter to arrange a successful scheme of workshop lighting. All that is required is the application of a few common-sense principles and to bear in mind the fact that the light should fall upon the object and not upon the eye; at the same time securing even illumination with freedom from heavy shadows and streakiness. There are now available a large number of specially designed reflectors and fittings for interior lighting which distribute the light in a certain definite manner; by spacing them properly it is possible to carry out the installation so that a successful lighting scheme will result. This need not entail any extra cost over the ordinary installation in which enamelled iron shades of the common pattern are used in an indiscriminate manner. Apparently the sole virtue of this class of shade is its cheapness; it does not shield the eye from the bright filament of the lamp, and owing to variations in the manufacture, no two enamelled iron shades will be found to distribute the light in an exactly similar manner.

Good lighting means cheap lighting. There should not be and need not be any waste. As regards the quantity of light, this depends entirely upon the class of work which is being carried out in the factory. Some trades, for example lithographing, engraving, etc., require a large amount of light, whereas in foundries it is much smaller. Expressing it on a per capita basis, even if so large a quantity of light as 100 c.p. per man is allowed, this at 4 cents per unit will only entail a cost of about ½ cent per hour. In the case of a skilled workman, earning say 25 cents per hour, it needs very little improvement in his output and quality of work for this cost to be recovered.

Considerations to be Accounted.

There are two considerations to be dealt with in all factories and workshops. First, with reference to the question of general lighting in shops, and secondly, the provision of local lighting for machines, lathes, tools, etc. In other cases, the point to be remembered is that the cost of carrying out the lighting scheme properly is insignificant, with the risk that is run of accidents, which, as has been mentioned, are largely the outcome of inefficient lighting. There is also the danger of the work being spoilt through inefficient illumination. Special trades and situations each require individual consideration. Some trades call for good general illumination only, others require in addition to general lighting, local lighting.

Illuminating Mediums.

The general illumination can be effected in three ways. (1)—by arc lamps; (2)—by mercury vapor lamps; (3)—by incandescent lamps. The first method is very suitable for large areas where the lamps can be installed high up. In general there are three types of arc lamps to be considered. (1)—Flame lamps burning mineralized carbons; (2)—enclosed lamps burning pure carbons; (3)—open lamps burning pure carbons. The uses of each may be summarized generally as follows:—

Flame lamps for very large interiors or for exteriors of shops where great illumination is required from an advertising standpoint. Enclosed lamps for small engineering shops and foundries where considerable intensity of the light is not required to be very great and the question of maintenance, the re-trimming of the carbons, is a difficulty.

Open type lamps have been largely displaced by the flame arc, but they may be used for large interiors where the ceiling is lofty and the walls are light colored and therefore of good reflecting power.

Mercury vapor lamps can be used for general lighting with excellent results wherever the color of the light is not objectionable. These lamps give, of course, a peculiar bluish white light. The principle upon which the lamp works is such that the light is diffused and softened to a much greater extent than with any other form of artificial light, although the nature of the light is such as to be unsuitable for color matching. They are exceedingly cheap to run, but somewhat expensive in first cost. A c.p. of 1,200 can be obtained from these lamps with energy at 6 cents per unit, at a cost slightly exceeding 2 cents per hour.

As a comparison, it may be mentioned that this is approximately 25 per cent. less than the cost with an open type flame arc lamp, but it must be remembered that with the mercury vapor lamp there is no additional expense to be added through the cost due to the labor required for re-carboning. Incandescent metallic filament lamps, because of their simplicity and the nature of the light, will probably be found most suitable when ordinary conditions only have to be considered. With their cost for current taken into consideration, the renewal of the lamps would be approximately 50 per cent. more than with a mercury vapor lamp.

Fitings and Reflectors.

The main factor in successful or otherwise lighting by incandescent lamps is the class of fitting or reflector with which they are used. In addition they should be properly spaced. The reflector has a most important effect upon the general illumination, and if the case of one particular pattern is considered it will perhaps lead to an understanding of the results obtained by a reflector when used in conjunction with an incandescent lamp.

With different shapes of reflectors the distribution of light can be altered according to varying requirements. For example, whilst one particular type of reflector would increase the candle power in a downward direction, directly below the pip of the lamp, another type of reflector is so arranged that the light is thrown in a sideways direction to the greatest extent, thus distributing the light over a much larger area. It is obvious that these various types have different applications which vary according to whether a diffused or an intense bright light in a certain direction is required; say for example, over a printing machine.—Electrics.

FRASER & CHALMERS, LTD.

Fraser-Chalmers, Ltd., of London, England, previously represented in Canada by Mussens, Ltd., have opened a Canadian branch office at 4 Phillips Place, Montreal. Arthur H. Sancton, formerly their engineer in Canada, has been appointed manager, and important additions have been made to the Canadian engineering staff.

The firm manufacture an extensive line of mining and power machinery, including high power gas engines, steam turbines, air compressors, steam and electric winding engines. Stumpf uniflow engines, conveyors and transporters, smelting equipment, concentrating plants cyanide plants, stamp mills and crushing machinery. They are the sole manufacturers of the Bettington Dust Fuel Boiler. This is a departure in boiler design which has been extremely well received.

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

Spur Gear Features

By G. D. Mills.

FIG 4 contains the method by which the true involute tooth curve is constructed. The points which define this curve are obtained by drawing a series of lines at right angles to the radiating lines from their point of intersection with the base circle of the involute curve, and length to be laid off on each is the circular distance measured on the base circle from the radiating line of flank of tooth to the commencing point. A very common mistake in forming this curve is to lay off the chordal distance. This robs the side of the tooth of a small portion of metal and also of its correct outline.

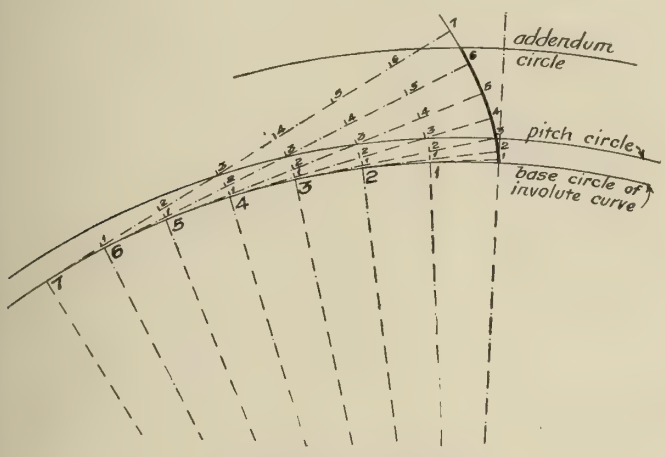

Fig. 4—Spur Gear Features.

The quarter circumference of the base circle should be divided into an equal number of parts and the greater the number the more correct will be the profile. The length of quarter circumference can be determined by multiplying the diameter of base circle by 3.1416 and dividing by 4, which length may be marked on a straight line and divided in the same number of parts as we have divided the quarter circle into. We thus determine on a straight line, the circular length of each division. This operation will not be necessary for normal wheels, as the difference will be found too small to warrant it; but in the smaller wheels it will be found necessary if a true profile be desired. The profiles of all gear teeth vary with every change made in the diameter of the base circle of the curve; and if the teeth are formed correctly they will interchange and roll off smoothly without digging into the flanks of the engaging wheel, a trouble largely due to defective profiles.

Duplication of Involute Curve.

Fig. 5 contains a true involute profile of a gear tooth, and a method by which we may duplicate the curve, in drawing the remaining teeth in the wheel. After the pitch circle and addendum circle have been described, and the angle of pressure defined by the line of pressure (a b), which in 14½ degrees obliquity will be 75½ degrees, we may draw the base circle of the involute curve tangent to (a b), or the radius of base circle can be calculated by multiplying the radius of pitch circle by .9681, from Fig. 3. The involute curve is then constructed as in Fig. 4, and the average inclination of the profile thus obtained, between points (c and d) is determined by means of circular arcs and the oblique line (e f), on which we may obtain a radius by trial which will fit the profile. Through the point so found for this radius on the line (e f), a circle should be described, which is the circle for centres of tooth arcs for the remaining profiles. If we hold the marking leg of the compasses on the pitch circle at the points defining the width of each tooth, and the other leg on the circle for centres of tooth arcs, the profile can be duplicated for the remaining teeth in the wheel. The fillet in the corners is formed by a radius which is equal to 1-7 of the clear distance between teeth on the addendum circle.

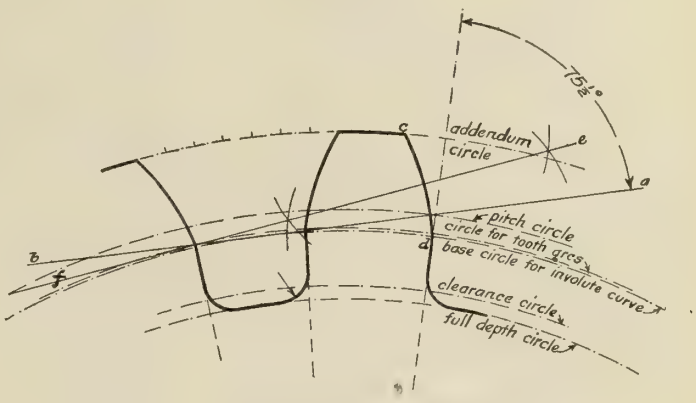

Fig. 5—Spur Gear Features.

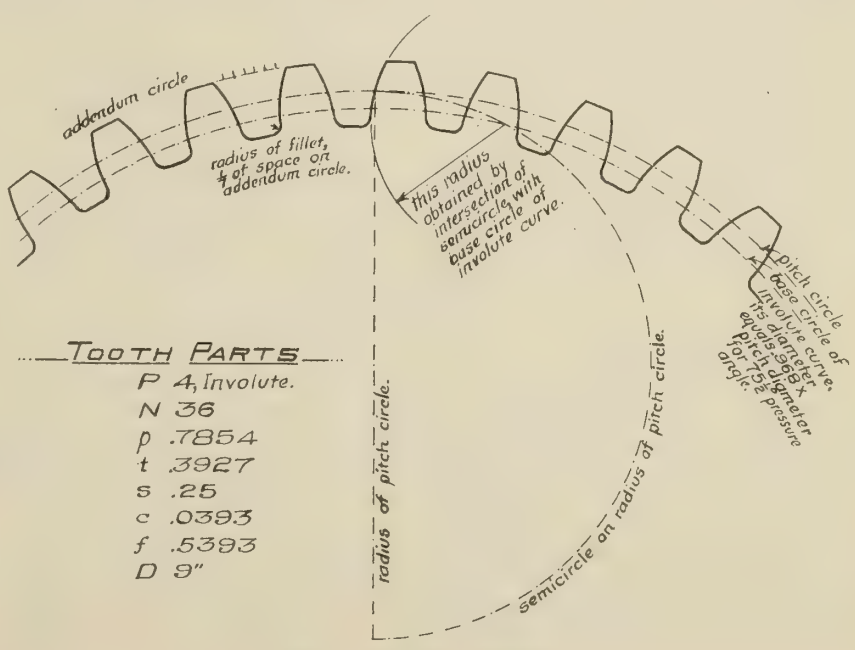
Method II, Involute Tooth Construction.

Fig. 6 contains another method by which involute teeth may be constructed



addendum circle
radius of fillet, ¼ of space on addendum circle.
This radius obtained by intersection of semicircle with base circle of involute curve.
pitch circle
base circle of involute curve.
Its diameter equals 9.68 × pitch diameter for 75½ pressure angle.
radius of pitch circle.

Fig. 6—Spur Gear Features.

and the profile thus obtained corresponds very closely with the true involute curve in normal wheels, while there is a noticeable difference in the coarser pitches of small wheels. This method is extensively used in the manufacture of involute gears, owing, perhaps, to the fact that it requires less time to construct than first profile. The lines of Fig. 6 are marked so that its construction is made plain. It will be noticed that the radius by which the curve is formed is equal to the length (c,d) of the triangle (a, c, d) in Fig. 3, and that the circle for centres of tooth arcs in Fig. 6 is the base circle of the involute curve. It will be found,

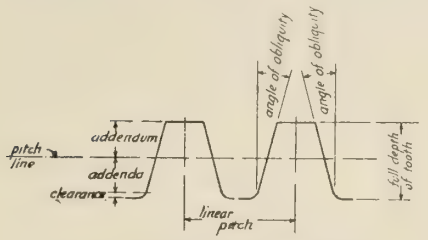

Fig. 7—Spur Gear Features.

however, that the radius by which the true profile is duplicated can rarely be made to fit the curve and fall on the base circle, although it will approach close to it, as in Fig. 5. The radius of fillet in corners is equal to 1-7 of the clear distance between teeth on addendum circle.

Fig. 7 contains a diagram of two involute rack teeth. The pitch line and linear pitch corresponds to the pitch circle and circular pitch in spur gear wheels. The width of tooth is laid off on the pitch line, equal to one-half the linear pitch, and the other tooth parts as in wheels. The meaning of the angle of obliquity is exemplified in involute rack teeth, since the sides of the teeth are straight lines inclined at an angle with the perpendicular; being the angle of obliquity of the engaging wheel. The only operation necessary to draw the teeth is to lay off the angle of obliquity with a protractor on each side of a line which is perpendicular to the pitch line, and parallel these lines through the points defining the width of teeth on pitch line. The radius of fillet bottom of tooth is equal to 1-7 of the clear distance between teeth on the addendum line.

Cycloidal Racks.

The sides of cycloidal rack teeth are composed of two curves, which are known as parts of a cycloid. The operation by which the curves are obtained is similar to that for wheels, except that the generating circle is rolled both sides of the pitch line instead of both sides of the pitch circle. The curves thus obtained are not pronounced, and the hurry-up method is frequently in evidence, when we see the sides of cycloidal rack teeth formed with straight lines, as in involute racks.

Calipering.

The width of each tooth in a wheel should be tested with a tooth gauge, or an adjustable caliper. In the illustration Fig. 8 is shown a gear tooth and part of a caliper. The jaws of the caliper are about the tooth, while the depth gauge rests on top of it. In order to caliper the width of the tooth on the pitch circle, we shall have to set the jaws of the instrument to a distance equal to the chordal length (b e d) which is less than half the circular pitch (or b c d). It will also be necessary to increase the length of the addendum (e f) and make it equal to (e f); adding the distance (e c) to obtain the correct length to set the depth gauge of the caliper. Both lengths may be readily calculated; if we consider the wheel a regular polygon and the teeth and spaces its sides. The angle which each tooth subtends at the centre of wheel is therefore

$$\frac{360 \text{ degs.}}{2 \times N}$$

and the half angle or angle

$$0 = \frac{360 \text{ degs.}}{4 \times N} = \frac{90 \text{ degs.}}{N},$$

in which N equals the number of teeth.

In the right-angled triangle (a e b) the radius of wheel (a b) or one-half the pitch diameter $\times$ sine 0 equals the half chord (b e) and, therefore, the pitch diameter $\times$ sine 0 = twice (b e) or the chordal width of tooth on the pitch circle (b e d). The length (e c) which must be added to the addendum (c f) is the versine of the arc (b c) and the increased length (e f) is, therefore [R $\times$ (1—cosine 0)] + addendum, in which R = radius of pitch

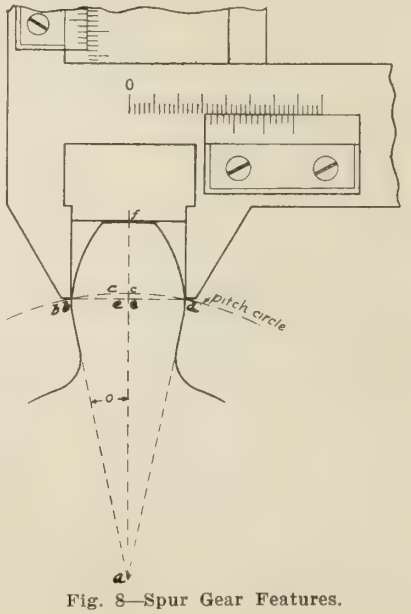

Fig. 8—Spur Gear Features.

circle (a b). The length (e c) is also the height of the segment (b, c, d, e), and may be calculated by the formula for heights of segments. The increased length, e f by geometry, therefore equals: $[-\sqrt{R^2 (R \times \sin. 0)^2}] +$ addendum, and R $\times$ sin. 0 equals the half chord (b e).

Caliper Formulae.

The following explains the application of the formulae. The caliper width and caliper depth of the tooth may both be determined from sine 0 with the formulae. In the example given previously in this article, Fig. 2, the half angle of tooth for the gear =

$$\frac{90 \text{ deg.}}{36} = 2\tfrac{1}{2} \text{ or } 2 \text{ deg} — 30',$$

and the half angle of tooth for the pinion =

$$\frac{90 \text{ degs.}}{12} = 7\tfrac{1}{2} \text{ degs. or } 7 \text{ degs} - 30'.$$

By referring to a table of sines, the sine of each angle can be ascertained.

CALLIPER FORMULAE.

$0 = \frac{1}{2}$ angle of tooth $= \frac{90^\circ}{N}$

Calliper Width of tooth $= D \times \sin 0$

" Depth " " $= [R \times (1 - \cos 0)] + s$

" " " " $= [R - \sqrt{R^2 - (R \times \sin 0)^2}] + s$

N = Number of teeth

D = Pitch diameter

R = Radius of pitch circle

s = addendum

$0 = \frac{1}{2}$ angle of tooth

The decimal part of the degrees should be reduced to minutes and seconds, if it will permit. The sine of 2 degs. — 30' is .0436, and the caliper width of tooth for gear = D $\times$ sine 0 = 9 $\times$ .0436 = .3924 inches. The sine of 7 deg.—30 is .1305 and the caliper width of tooth for pinion = 3 $\times$ .1305 = .3915 inches. The caliper depth of tooth for gear by geometry = $[R - \sqrt{R^2 - (R \times \text{sine } 0)^2}] + S = [4\tfrac{1}{2} - \sqrt{4\tfrac{1}{2}^2 - 4\tfrac{1}{2} \times .0436)^2}] + .25 = (4\tfrac{1}{2} - 4.4957) + .25 = .2543$. The caliper depth of tooth for pinion $= 1\tfrac{1}{2} - \sqrt{1\tfrac{1}{2}^2 - (1\tfrac{1}{2} \times .1305)^2}] + .25 = (1\tfrac{1}{2} - 1.48717) + .25 = .2628$. The operation for determining the caliper depth of tooth may be shortened by using the cosine of each angle in the table of sines, and applying the formulae [R $\times$ (1—cosine 0)]+S, by which the same results are obtained. The caliper depth of tooth for gear=$[4\tfrac{1}{2} \times (1 — .99904)] + .25 = .2543$ inch, and the caliper depth of tooth for pinion = $[1\tfrac{1}{2} \times (1 - .99144)] + .25 = .2628$ inch.

It is as important and necessary to caliper each tooth in a wheel as any other operation connected with its manufacture, but no amount of caliper-

ing will detect inequalities in spacing. Keying troubles, which are so common in all gears, may be traced mainly to defective spacing of the teeth.

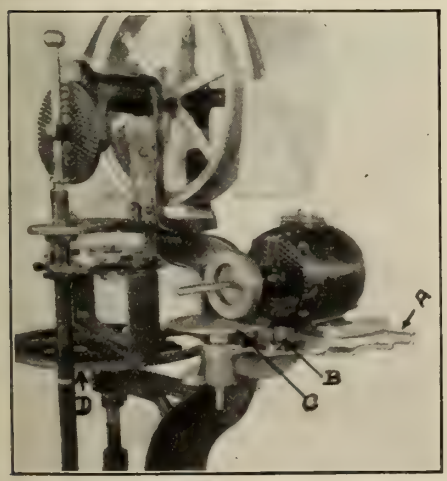
The profiles of Brown & Sharpe cycloidal gear cutters are supposed to be geometrically correct, as the profile is obtained by means of a machine known as the Odontom engine, which rolls generating circles with mechanical as well as mathematical accuracy. The profile of the cutter is that of a space between two teeth which it mills out. The number of teeth and diametral pitch determine the profile of the cutter. As the pitch diameter of the wheel varies with these two quantities, $D = \frac{N}{P}$, the difference in the profile of one diametral pitch and two numbers of teeth is well illustrated in the reduced cut, Fig. 2, previously published. The pitch is 4 diametral, and the profile of the 12-tooth pinion is noticeably different from that of the 36-tooth gear.

VARIABLE SPEEDS FROM A CONSTANT SPEED MOTOR.

By E. W. Tate.

THE half-tone illustrates the method used to obtain variable speeds from a constant speed motor. The latter was originally placed on a bracket, similar to that shown, with a grooved pulley of two diameters on the armature spindle.

For conversion purposes, the original base was discarded and a gibbed base substituted. A leather friction and disc were used in place of the grooved pulley, and in the base was placed a gear, keyed to a vertical stem, on the opposite end of which was attached the lever (A). The gear was meshed into rack (B),



Variable Speeds From a Constant Speed Motor.

which in turn was secured to the under side of the motor. A movement forward or back of the lever (A) increased or decreased the speed of the disc (C), which transmitted power to the machine through the grooved pulley (D).

REAMER HOLDER.

By R. G. D.

SOMETIMES, in a large factory, situations lead to interesting results in the methods used to solve different manufacturing problems. I have in mind a case which is almost universal in automatic screw machine work, the floating bushing method of holding reamers and counter bores, as illustrated in Fig. 1. It is the writer's experience that work machined in this way is apt to show large at the end; that is, the bore will be slightly larger at the commencement of the operation, due to the fact that the reamer is free to sag below the centre of the work. This causes it to "wobble" and cut large until such time as it has reached a depth sufficient to support it, when of course the trouble ceases.

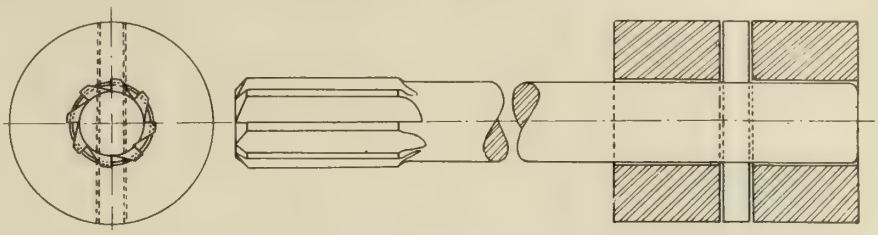


Fig. 1—Reamer Holder.

To eliminate this trouble we devised the reamer holder shown in Fig. 2, which is almost self explanatory. A, the body, is held at the turret, and centre B adjusted until it takes the thrust; the pin C simply being the driving member. The action of this tool is such that it centres itself immediately upon entering the work, as can be readily seen. It may be interesting to add that since using this device, our scrap has decreased to a very marked extent. I would say that about six months after this tool was designed, we found one almost exactly like it in "Rose's Complete Machine Shop Practice," although at the time no one knew of any such tool; all of which goes to show that there is nothing new under the sun. This is written with that idea in mind.

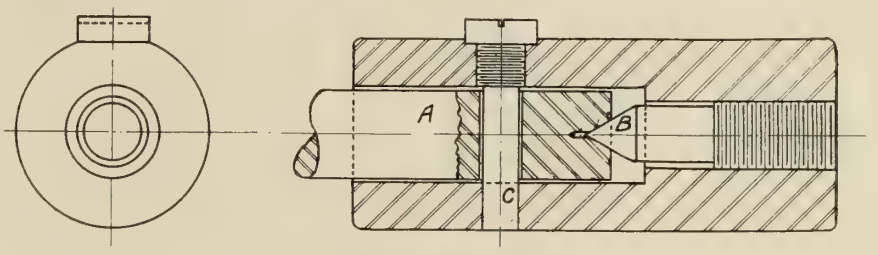

Fig. 2—Reamer Holder.

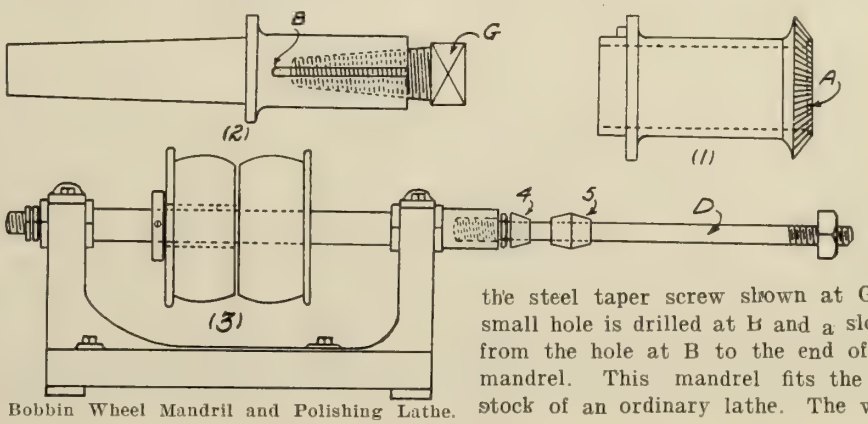
BOBBIN WHEEL MANDREL AND POLISHING LATHE.

By G. Barrett.

THE following article will no doubt appeal to readers of Canadian Machinery, who are interested in the manufacture of bobbin wheels for textile machines. The primary operations on these bobbin wheels, namely boring and rough turning, present no great difficulties, so particular attention will be paid to the finishing methods.

No. 1 shows the wheel as it appears when fully machined. After being bored and rough turned they are very fragile, as all the scale has been removed. Thus, in driving them on and off a mandrel in the usual way, a great many are broken To reduce this, I made the mandrel shown in No. 2. It is made from tool steel and is bored, and tapped to suit the steel taper screw shown at G. A small hole is drilled at B and a slot cut from the hole at B to the end of the mandrel. This mandrel fits the headstock of an ordinary lathe. The wheels



Bobbin Wheel Mandril and Polishing Lathe.

are placed on the mandrel in the lathe, and one turn of the screw G is sufficient to secure the bobbin wheel sufficiently for it to be skimmed up and recessed as shown at A. A great deal of time is saved at each change of wheels, because all the pounding on and off mandrels is eliminated.

Bits of cotton adhere to these wheels if they are not smooth, therefore I made a polishing lathe as shown in No. 3. Eight wheels can be polished at a time. The extended spindle D is $\frac{7}{8}$ in. diam. The wheels vary in outside diameter from 1 to $1\frac{1}{8}$ in., and to accommodate several sizes on the spindle at once, the cones shown at 4 and 5 are used. A single cone similar to 4 is first placed upon the shaft, then a wheel, then a double cone and so on, until the spindle is full. The nut is afterwards tightened and the wheels polished. The mandrel described above and also the polishing lathe are often used for collars and brushes.

AUTOMOBILE TRANSMISSION GEAR.

By A. W. Cookson.

THE main drive gear as used on several makes of automobile transmission of the sliding gear type is shown in Fig. 1, and the method of machining it, as adopted in a prominent automobile factory, is here described.

The part, a drop forging of chrome vanadium steel, is first machined on the outside on a Lodge & Shipley manufacturing lathe with gang cutters. It is then reversed and held in the chuck by the shank, after which the large outside diameter of gear, hole (A) and relief for the coupling, are machined. It has been found that the work at this stage is accurate enough for the outside diameter of the gear, but owing to internal strains within the forging, it is not practical to finish cutting the teeth until after carbonizing, which process while relieving all the strains, generally distorts the piece. The teeth are, therefore, rough cut, leaving a small amount, about .010, on each side, to be taken out later. All the other operations are, however, done, except the grinding and keyway cut. The coupling is finished and backed off, the holes being drilled and the thread cut. The part is next carbonized, but not hardened, and returned to the gear cutter, where the teeth are finished to size. The turned surfaces (B and C) are, however, not in good shape to use for holding the gear for this final cut on the teeth. They are, therefore, rough ground, leaving a small amount for the final grinding after hardening.

It is, of course, necessary, if the complete gear is to be up to the standard required in modern automobile manufacture, that the part be held very rigid in the chuck for this final gear cutting operation. The writer designed the chuck shown in Fig. 2 to do this work. The construction is clearly shown in the sectional view and needs little explanation, other than to say it is necessary to use care in making up the chuck so that the work will be held central. In use, the gear is pushed back into the chuck uptil the face (D) strikes the flange on the spring collet. The hood (F) is then screwed up until it compresses the outer spring collet (B) on to the bearing (H), when the further movement of the hood will cause the collet and also the gear to move back into the chuck and so tighten the back collet (C) on to the other bearing (J). The collets (B and C) being independent of each other will allow for a small variation in diameter of the two bearings and still hold well, which would not be the case were one collet only used to draw on both bearing surfaces.

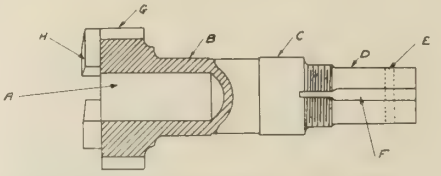


Fig. 1—Main Drive Gear, Automobile Transmission.

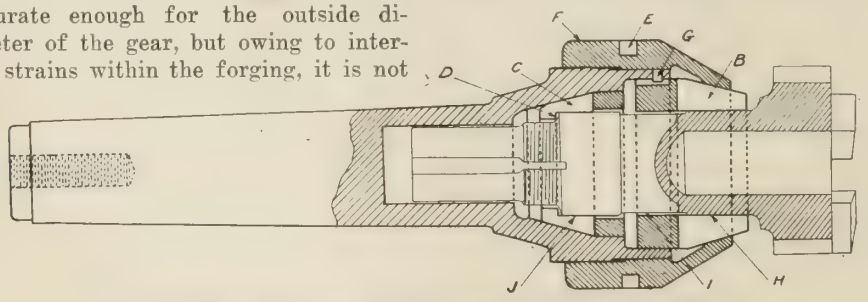

Fig. 2—Chuck for Main Drive Gear, Automobile Transmission.

A pin (G) has been provided to prevent the front collet turning, and so changing the position of the gear in the chuck, as being readily understood that the gear must be placed in proper relation to the cutter for this operation of finish cutting. The holes (E) are spanner holes for tightening the hood. The taper shank is fitted to the gear cutter spindle and is a standard B. & S. taper, but it can, of course, be fitted to any machine. It will be found that this chuck will hold well under any ordinary condition. After the last operation of gear cutting, the gears being reheated and hardened, are then ready for the final operation of grinding. The surfaces (B, C and D) are first ground, the work being held in a special chuck designed to hold the gear by the root diameter. This surface is, when using a form cutter, always concentric with the pitch diameter.

A chuck of same design as. Fig. 2, but with a shank fitted to the grinder, is used to hold the gear for the operation of grinding the hold (A) and for grinding the bushing when in place. With reasonable care in keeping the chucks free from dirt and chips, the above method of machining will result in a gear that will be true to pitch and with the pitch line concentric with all the bearings; and, providing the other gears into which this part will mesh are cut with the same amount of care, will insure a silent running transmission.

AN UNLISTED CALIPER.

By T. R.

LATHE hands at some time or other in their experience have performed work which has caused them more or less hard thinking and worry as to correctness of requirement and economy of production time. One such job may have been a casting or forging for a boiler manhole strengthening plate, which, when completed on the lathe, should have a certain definite radius. With, possibly, only a small arc of the latter turned, absolute accuracy cannot be determined unless a radius gauge be applied, and even then, much time may be lost in the process. By means of the caliper illustrated and application described, it will be found possible to produce work of such a nature both correctly and expeditiously.

Set the caliper to the amount of the radius and place tool in rest. Mark the work, by revolving in the usual manner, with a surface gauge set to height of tool point. After setting the job opposite to and at its furthest point from the tool and with the inside caliper leg at the tool point, set the outside caliper leg to the mark made by the surface gauge.

"Men who hold office must work hard!" Whether in the service of the State or of industry, it, furthermore, means that one must devote a full measure of work and thought to the duty owed to the safety and welfare of those who are dependent upon us for their wages.—Ex.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

SPECIAL PAPER BAG MACHINE.

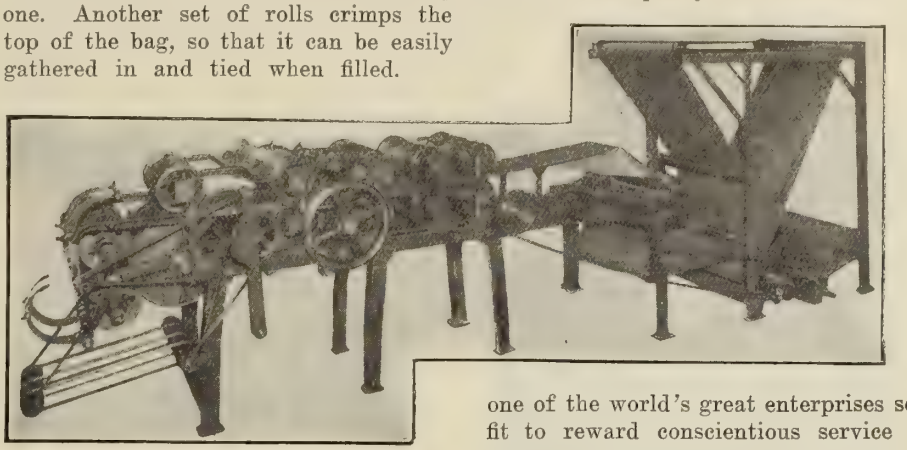
MACHINERY is being employed in such a multitude of directions to replace hand labor, that there seems no limit to its adaptability. Special machines have become everyday occurrences, and as a consequence in a great many cases they command attention but for a brief period.

Recently, the Holden-Morgan Machinery Co., Pearl Street, Toronto, built for the Standard Chemical Co., a machine which takes a roll of paper of certain width, passes it through a small printing press, cuts, applies paste, and folds the paper; finally transforming the latter into a bag all ready for use. The very ingenuity of the machine, coupled with a neat and clean cut appearance, causes one to pause in admiration. The apparatus is now installed in Montreal, and is reported to be doing even more work than that for which it was designed.

The roll of paper is placed on the spindle provided for same; the first operation thereafter being that of printing the trade mark, or name of contents, maker's name, etc. It then passes over two rolls, during which process the ink is allowed to dry. Afterwards a revolving disc, which dips into paste, applies

An Unlisted Caliper.

this latter to one edge of the paper. From these rolls it is folded over a steel plate to form a tube and thence it enters a series of rolls, the first of which presses the two edges together, the paste causing them to stick. The first cut, that of a very flat "V" with a sawtooth line, forms part of the bottom of one bag, and the top of the following one. Another set of rolls crimps the top of the bag, so that it can be easily gathered in and tied when filled.



Special Paper Bag Machine.

The next operation takes place in the rolls, which do the side cutting. Here, the bottom of the bag is prepared for the "diamond fold." A set of rolls now applies paste to the bottom and from there it passes on to the final fold which brings the adhesive qualities of the paste into play. The bottom is afterwards flattened, that is, turned at right angles to its natural position when full. The bags now pass out of the rolls to a conveyor belt, which deposits them in a neat pile.

The prime mover is an electric motor, and a chain and two sprocket wheels connect the press to the machine proper. All of the rolls are driven by a train of spur gears on one side of the machine.

The apparatus is used for making charcoal bags, and although only designed to turn out fifty a minute, it is being operated at a slightly higher capacity. The machine with slight alterations in design can be made to produce any size bag, and is particularly well adapted for making bags for flour and feed mill products.

INDUSTRIAL PROGRESS.

The fact that Armour & Co. have set aside a fund of a million dollars for the inauguration of a pension plan for employes is significant, not so much as regards the amount involved, but rather as exemplifying the tendencies of our great industrial factors in the direction of humanitarianism. There are 55,000 employes of Armour & Co. A million dollars, perhaps, will not go very far, but that is not the point. It is rather the fact that the policy of the directors of one of the world's great enterprises sees fit to reward conscientious service by eliminating the worry for future livelihood. Such movements in the great American industrial field will do more to eliminate impractical socialism than all the propaganda that could possibly be advanced by dreams of Utopian impossibilities!

THE AMERICAN INSTITUTE OF METALS.

The result of the ballot on the question of changing the name of the American Brass Founders' Association to that of the American Institute of Metals, showed that out of 108 votes cast, 93 were in favor of the new title, and only 15 against. In view of the foregoing, the new name will be assumed just as soon as the necessary arrangements and announcements can be made.

The ballot, concerning the time and place of the annual convention, resulted in 92 votes being registered in favor of allowing the executive committee to determine the selection, and 16 votes against out of a total ballot of 108 votes cast.

The name of the Advance Machine Works, Limited, Walkerville, Ont., who are builders of Northern Cranes and Hoists in Canada, has been changed to Northern Crane Works, Limited. The company will continue the manufacture of cranes, hoists, etc., as heretofore.

They have recently completed a new plant at the corner of Argyle Road and Essex Terminal, in Walkerville, and report a large number of contracts in progress.

C.N.R. Double Truck Type Gas-Electric Motor Car

By H. A. Wilson

Canadian railroad enterprise is prominently exemplified in the accompanying article, and the success which has attended the efforts of those directly concerned will doubtless awaken widespread attention to and investigation of the possibilities of this motor in other spheres.

THE rapidity with which the internal combustion engine has arrived at its present state of perfection has caused a great many to be more or less sceptical of its reliability. However, rapid as has been its perfection of details and design, its field of usefulness

Operating and Control Equipment.

has been increasing with equal rapidity. The latest application on Canadian soil takes the form of a gas-electric car for use on the shorter lines of steam railways. The car consists of a gasoline engine driving an electric generator which supplies current to the motors mounted in the trucks of the car.

General.

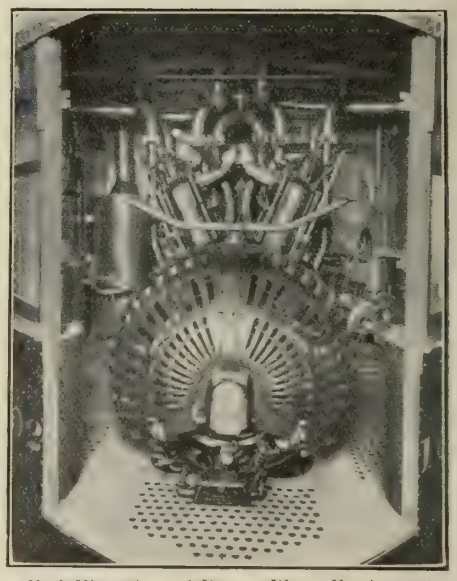
The engine is a 200 h.p. machine of the four-cycle type, having eight cylinders in two rows of four each. The cylinders are inclined from the vertical about 30 degs., and are "staggered" so that they can all be connected to a common crank shaft. They are also cast singly with separate heads. The heads are secured by long bolts through the cylinder directly to the crank case. The valves are operated by two cam shafts; one on each side of the engine looking after its set of four cylinders. Both intake and exhaust valves are situated in the heads of the cylinders, thus necessitating the use of rocker arms to actuate them.

Fuel.

Gasolene is generally used as fuel but "Painters' Naphtha" has been extensively employed in the operation of these cars in the States. Two carburetors are used, one large and one small. The large one takes care of the engine when the car is running under ordinary conditions; the small one being used when the car is coasting or when for other reason the engine is not called upon to deliver much power.

The Engine.

The cylinders are 8-inch. bore with a 10-inch stroke. The engine base or crank case, of cast iron, is fitted with large hand holes, the covers of which can be readily removed to inspect the main bearings and large ends of the connecting rods. The cylinders are of close-grained grey cast iron, developed especially for gas engine requirements. The main exhaust valve is located in the cylinder head, as before stated, but an auxiliary exhaust port in the side of the cylinder is uncovered by the piston as it reaches the end of its stroke. This exhaust port naturally assists in ridding the cylinder of all the burned gases. Each piston is of the trunk type, cast iron, and is fitted with snap rings of the same material. The wrist pins are of hardened steel, ground to size and clamped in the ends of the connecting rods. The bearings, of phosphor bronze, are in the piston. The connecting rods are of high carbon steel, drop forged and heat treated. The crank shaft is also made of high carbon steel and heat treated; with the coupling for connecting to the dynamo shaft forged integral. The bearings consist of bronze cages lined with babbitt, as also are the large ends of the connecting rods. A system of forced lubrication



End Elevation of Power Plant Equipment.

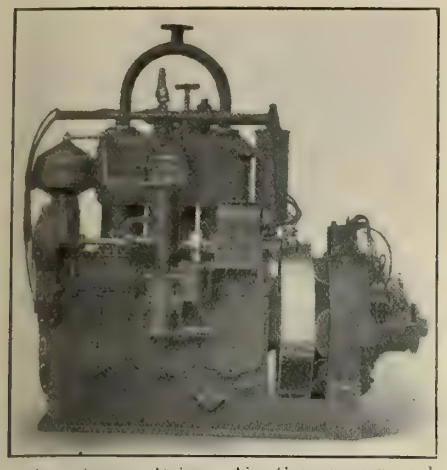
provides for the oiling of the cylinders and all the bearings, through ducts in the crank shaft.

Carburetor.

The gasoline tank, the capacity of which is 100 gals., is situated under the body of the car. Consequently, the level of gasoline in the fuel chamber of the large carburetor can not be maintained by gravity and a cork float as is the common custom. The supply is delivered by a pump, and the surplus taken care of by overflow pipes leading back to the fuel tank. The carburetor is of the multiple venturi type. Warm air is

C.N.R. Gas-Electric Motor Car.

supplied to the carburetor in cold weather. It is also used to ventilate the crank case by a suitable connection. Great precaution is taken to prevent dirt, dust or other foreign matter from finding its way to the carburetor.



Gas Engine Driven Air Compressor and Lighting Generator.

Strainers are provided at both inlet and outlet of the main gasolene tank. When the engine is not in motion, gasolene can be pumped to the carburetor by hand.

Ignition.

The ignition system consists of two low tension magnetos and magnetic make-and-break spark plugs. These latter are situated in the heads of the cylinders. Centrifugal switches are provided in the ignition circuits which prevent the engine from exceeding a safe speed.

The engine is water cooled, the radiator being situated in the roof of the car and circulation obtained by the thermo-syphon system. The radiator is of the five-tube type.

Air Compressor.

Connected to the engine is an air compressor, which provides air for the brakes and also for starting the engine, it being too cumbersome a machine to crank by hand. It consists of a single air-cooled cylinder 4-inch bore by $4\frac{3}{4}$ inch. stroke, driven from the crank shaft. When the engine is running at normal speed the compressor has a displacement of 22 cu. ft. of free air per minute. An automatic governor is attached and maintains a constant pressure in the air reservoir.

Generator.

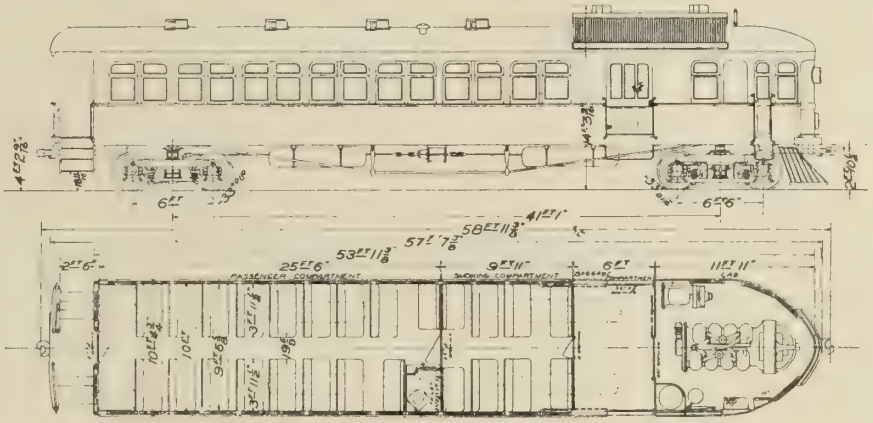
Direct-connected to the engine is an eight-pole, 600 volt commutating pole electric generator. The magnet frame is bolted directly to the end of the engine frame. The outboard bearing is ring-oiled and supported by a three-arm bracket. The design of the generator is standard with the slight alterations required to make it adaptable to the before-mentioned service conditions. This generator is designed to run at 550 r. p.m.; being the speed at which the engine delivers its rated power.

Motors.

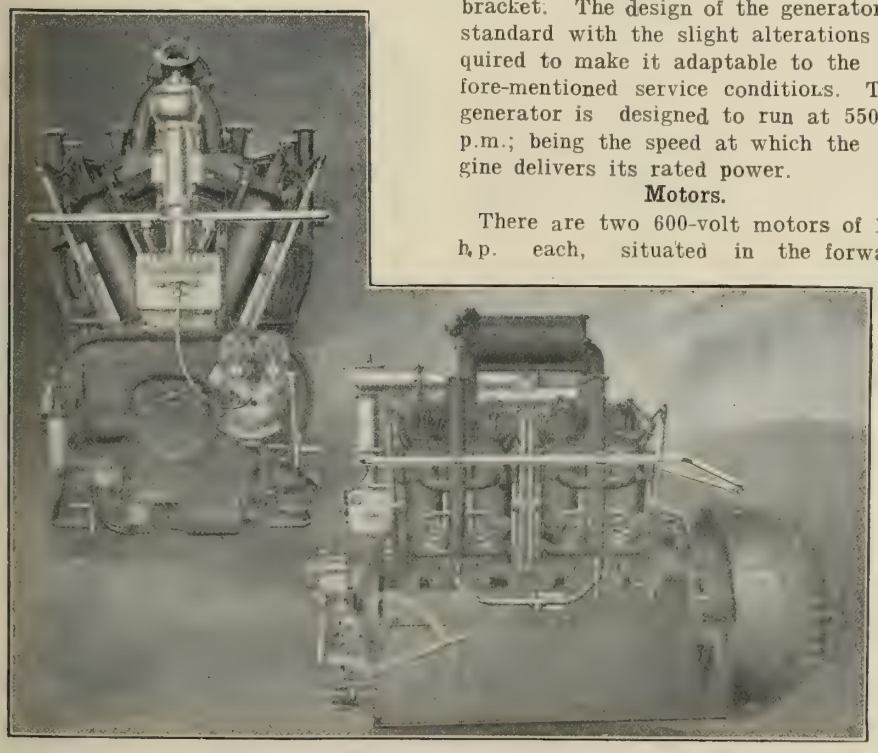
There are two 600-volt motors of 100 h.p. each, situated in the forward truck, one on each axle. Both front axles are, thus, driving axles and support from 65 to 70 per cent. of the total weight of the car; an important feature on grades or slipping rails. The motors are box frame, oil lubricating commutating pole railway type, equipped with standard gears and cases.

Control.

The control is of a very simple type; starting being accomplished by compressed air. The throttle lever being opened one notch, delivers air to the engine and causes it not only to start but to attain nearly its normal speed. Then, as the throttle is opened wider, the gasolene is fed to the engine. The motor-control handle is placed just above the throttle lever, and is of a special type; the driving motors being placed progressively in series and in parallel, and the voltage governed by varying the strength of the generator field. A separate handle is provided for reversing the car. On the engine, a lever is provided for advancing or retarding the spark. Hand brakes are provided in addition to the combined straight and automatic air brakes. All fittings, such as hose, gauges, etc., are provided; the gauges being placed on the board immediately in front of the driver, so that he will at all times be aware of the exact pressure in his air tanks. An air whistle and a pneumatic gong form part of the equipment of the car. The ability to instantly reverse the motor furnishes a means independent of the air or hand brakes of stopping the car in cases of emergency. The electrical control furnishes an infinite number of gear ratios without change gears, which gives the car a smooth and rapid acceleration.



Sectional Plan and Elevation, C.N.R. Gas-Electric Motor Car.



End and Side Elevations of P ower Plant Equipment.

Lighting Unit and Auxiliary Air Compressor.

The car has a small auxiliary engine which operates an auxiliary air compressor and supplies power to a dynamo for lighting purposes. This engine is a four-cycle, two-cylinder vertical gasolene unit. The air compressor cylinder is placed between the two-engine cylind-

ers, as shown in the accompanying cut, and is cast in a single piece, provided with a common water jacket. The diameter of the engine cylinders is 4¾ inches and the compressor cylinder, 5¼ inches; the common stroke being 6 inches. The cylinders are of the T head type, that is, the combustion chambers overhang the cylinders on both sides; the exhaust valves are placed on the opposite side to that of the intake valves and usually only require one link, namely, the push rod to connect the cam to the valve stem which is forged integral with the valve. Thus, two cam shafts are required, one to operate the intake valves and one to operate the exhaust valves. This compressor cylinder has a displacement of 45 cu. ft. of free air per minute, which is also stored in the tanks under the body of the car. The air is used to charge the tanks and start the main engine when the car has been idle for some time and there is not sufficient air remaining in the tanks to do this. The small engine is easily cranked by hand.

Directly connected to this engine is a 125-volt generator of 1½ kilowatts capacity. This generator supplies the current required by the interior incandescent lights and the 50 c.p. headlight. A centrifugal governor is provided which keeps the speed at 600 r.p.m. The connecting rods are of high carbon steel, drop forged and heat treated. The lubrication is effected by means of a constant level splash system. The ignition system consists of a low tension magneto with magnetic make-and-break spark plugs which are interchangeable with those on the main engine. Batteries are supplied to facilitate hard starting. The generator armature is bolted to the flywheel on the end of the crankshaft. The valves in the compressor cylinder are automatic in their operation and are both in the head of the cylinder.

The Car.

The distribution of weight is approximately as follows:—

	Pounds.
Body	33,000
Trucks	20,000
Motors and control	8,500
Gas engines and accessories	24,000
Passengers (60)	8,400
	93,900

The total weight thus approximates 47 tons.

The car can negotiate all grades up to 1½ per cent. with comparative ease, and can be driven up to about sixty miles per hour, but will travel forty-five with no difficulty whatever. When the service demands, it will pull a trailer.

One great factor which is manifest when negotiating grades and running in deep snow is that the tractive effort of the car remains constant regardless of its speed, provided the engine speed is maintained. All the engine parts are readily accessible in case of renewals or adjustments. Then, too, the engine is mounted on the floor frame of the car and all sudden jars are absorbed in the springs and are not transmitted to the engine. Dust and dirt do not readily find their way to the reciprocating parts, thus eliminating a great deal of wear.

The maintenance of the car is very low indeed. About two miles on a gallon of gasolene is the figure arrived at, after exhaustive tests over a considerable period of time. The crew consists of but two men, a motorman or engineer, and a conductor. The total operating cost in Canada will probably average about 20 cents per mile, but will vary a great deal according to local conditions, such as grades, distance between stops, traffic, etc.

The car is heated by hot water; the water being heated in a hot water heater in which anthracite coal is burned. This heater can be connected to the water cooling system of the engine when the car remains idle over night in cold weather, thus preventing the water from freezing in the radiator. As there is no smoke or cinders in connection with the power plant, the windows can be opened in warm weather. The engine is well muffled and the car runs with little noise and vibration.

This type of car is in no way an experiment, because similar types have been operated on American roads for a considerable time back. The car, however, has excited a great deal of interest and many people are closely watching its performances. On Saturday, April 13th, after trial trips had been run, it journeyed to Trenton on the new Toronto-Trenton line and ran between Trenton and Picton on the Central Ontario road which is now owned and operated by the Canadian Northern Railway, the owners of the car. On this route it was necessary to haul a trailer to care for the traffic. An ordinary railway coach was coupled on and the car carried the additional load to the satisfaction of all. The Canadian Northern intends to use the car near Quebec during the summer on tourist traffic.

CAN. FAIRBANKS-MORSE CO., LTD., MONTREAL.

Lewis C. Randolph has been appointed advertising manager of the Can. Fairbanks-Morse Co., with office at Montreal. Mr. Randolph is a graduate of Hampden Sidney College and Virginia Polytechnic Institute, and in addition to an engineering experience of several years, he has been on the staff of the Railway Age Gazette and advertising manager of the Corrugated Bar Co., Buffalo.

CONSUMPTION OF COAL IN CANADA.

In 1911, the total consumption of coal in Canada amounted to about 24,408,000 tons, made up as follows:—9,800,000 tons produced in Canada and 14,600,000 tons imported. According to the figures Canada produces only 40.2 per cent. of the coal which it consumes. It must be noted, however, that if all the coal mined in Canada had been used in the country, it would have constituted over 46.2 per cent. of the consumption.

The consumption of coal in Canada has increased from 3,450,111 tons in 1886, to 24,400,000 tons in 1911. During the same period the coal consumption per capita has increased from 0.758 tons to 3,389 tons.

NOVEL TYPE LOCOMOTIVE.

A novel type of locomotive is being developed under the patents of James Dunlop, of Glasgow. It is driven by compressed air, which is supplied by an oil engine-driven compressor. The compressed air is used on the closed circuit, sometimes called the dense-air system, in which a certain quantity of air passes continuously from the compressor to the engine or driving air motor, and then back to the compressor again. Leakage is automatically made up by a small auxiliary compressor. It is claimed that the closed-circuit system is more efficient than the open-circuit system, in which fresh air is continually being taken in by the compressor and the exhaust from the motor ejected to atmosphere.

In the closed-circuit system the average air pressure throughout the system is maintained at some definite figure, say 150 lbs., per square inch, the intake pressure at the motor being higher and the outlet lower. The range of pressure is governed by the control of the compressor and the cut-off of the motor. The compressor may be controlled by varying its speed, but more usually by altering the number of cylinders in action, this being done by lifting the air delivery valves off their seats in those cylinders to be put out of action. The air in the delivery main is then merely drawn in and pushed out through the open valve.

It is claimed that the fuel cost will be $2.11 per 1,000 effective horse-power hours with oil at $9.75 a ton, as against $3.75 for a steam locomotive with coal at $2.43. These costs are based on 0.5 lbs. of oil per B.h.p. at the engine, a recovery of 16 per cent. of the heat in the exhaust gases, and a mechanical efficiency for the locomotive of 90 per cent.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

SWEEP MOULDING AN OIL TANK IN GREENSAND.

By J. H. Eastham.

THE oil tank shown in plan and section views at Fig. 1 was urgently required to complete an order for elevator castings. The pattern

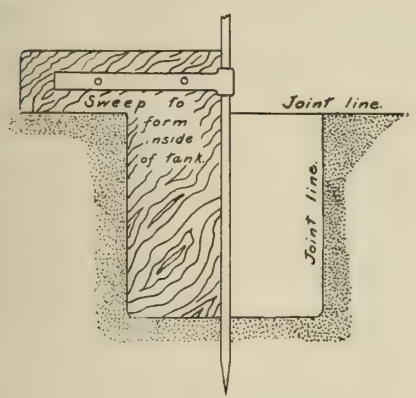


Fig. 2.

store having been thoroughly but unsuccessfully searched for the complete pattern formerly used it was concluded that the latter had been lost or accidently broken up and privately commandeered.

To secure speedy delivery, therefore, the sweep shown by Figs. 2 and 4 was made; the seating brackets, bosses and inside flanges being loose and bedded to

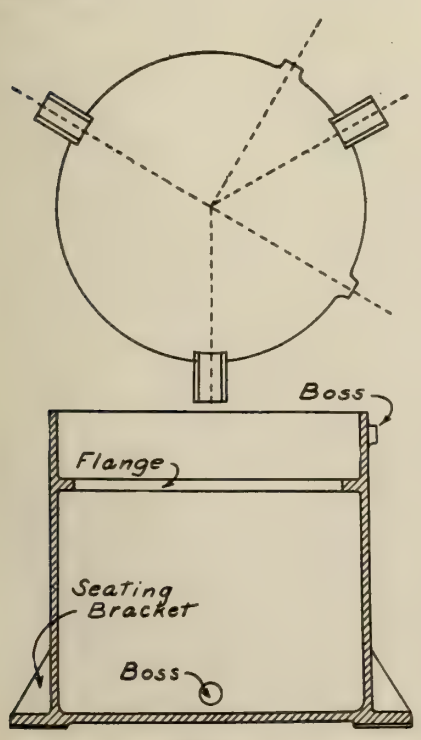

Fig. 1.

correct place by measurement. The sweep, with thickness piece removed, was bolted to the spindle arm, as shown at Fig. 2, then a bed, the exact size of the inside of the casting required, was strickled out and lined up with parting sand. A layer of facing sand one inch deep was next spread over the bottom, and the lifting grating shown by Fig. 3 stamped down on this; the inside being rammed-up to the depth shown. The six sections of flange forming the full circle were afterwards bedded, well ironed over and under and the ramming of the core continued to the top of the lifting eyes.

The cope was now lowered to place and rammed up in the usual way; a hook bolt being passed under the bend of each lifting loop attached to the grating and packed tightly by fish plates and suitable washers. The cope with core attached was then removed and

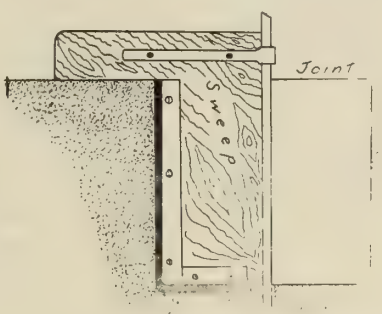

Fig. 4.

turned over to permit of necessary finishing; the inside of the drag mould being scraped away to allow placing in position the sweep with thickness piece attached, as shown by Fig. 4. The mould having been strickled to full outside width of casting, the sweep was again removed and the three seating brackets bedded to place, ironed in corners, vented and drawn inward.

Following this operation, the outlet boss was bedded in the side of the mould, its centre being two inches from the bottom and equidistant from two seating brackets. The inlet or feed boss was next located at right angles to the outlet, its centre being two inches from the top of the rim. Both cope and drag having been coated with plumbago blacking, the former was next washed with molasses water, skin dried, tried on, and inspected with a view to finding possible crushes; clay "finders" being placed at intervals on the bottom face to show thickness of metal allowed. These removed and minor defects corrected the cope was lowered again to position, weighted and the piece poured.

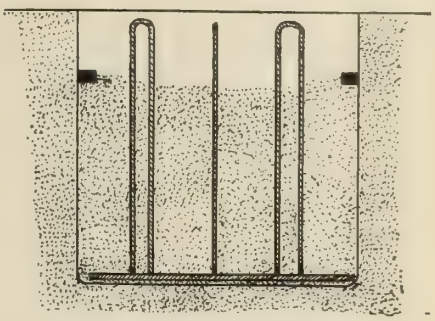

Fig. 5.

STEEL CASTINGS.

A LECTURE on "Steel Castings" was delivered before the London branch of the British Foundrymen's Association by Mr. H. Brearly, of the Brown-Firth Research Laboratory, Sheffiled. It was pointed out that the coarse crystalline appearance, which the fracture of steel casting was supposed to have, was not now a sufficient distinction between castings and forgings. Examples of the coarse crystalline fracture of a steel casting was suppposed to slowly cooled were exhibited, and also illustrated by lantern slides, side by side with portions of the same casting after heat-treatment. The exposed fractures

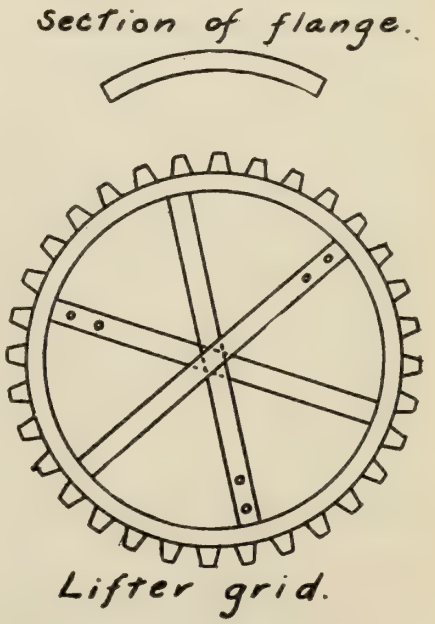

Fig. 3.

of the latter were in all respects indistinguishable from well-wrought forgings. The lecture was mainly devoted to the processes involved and the structural changes taking place between these two extremes.

The lecturer emphasized the workshop value of careful observation of fractured and prepared surfaces with a hand lens or any other available magnifying outfit, and then showed by a series of low-power photographs the wonderfully perfect structure of the interior of separate crystalline grains of mild steel. By the same means, the defects arising in and about the crystalline grains were demonstrated, and a clear impression conveyed of the objects to be attained by annealing.

The portion of the lecture which dealt with the fragility of unannealed steel castings was well illustrated and conveyed a clear reason for their erratic behavior. The lecturer thought it highly undesirable that unannealed castings should be brought into any kind of service where trustworthiness was called for; and showed, quite apart from the question of cooling stresses, how they might be expected to fail and how the important question as to whether or not a casting had been successfully annealed could be determined by simple means. The main object to be accomplished by annealing was said to be the elimination of the coarse crystalline structure, due to cooling from the liquid state, and the substitution of a much finer structure by methods which varied with the composition of the steel. Some very clear slides illustrated the hindrances, which occurred in uncontrollable ways, and prevented the attainment of this object, and led also to that kind of rupture between the crystals known to the foundryman as pulling.

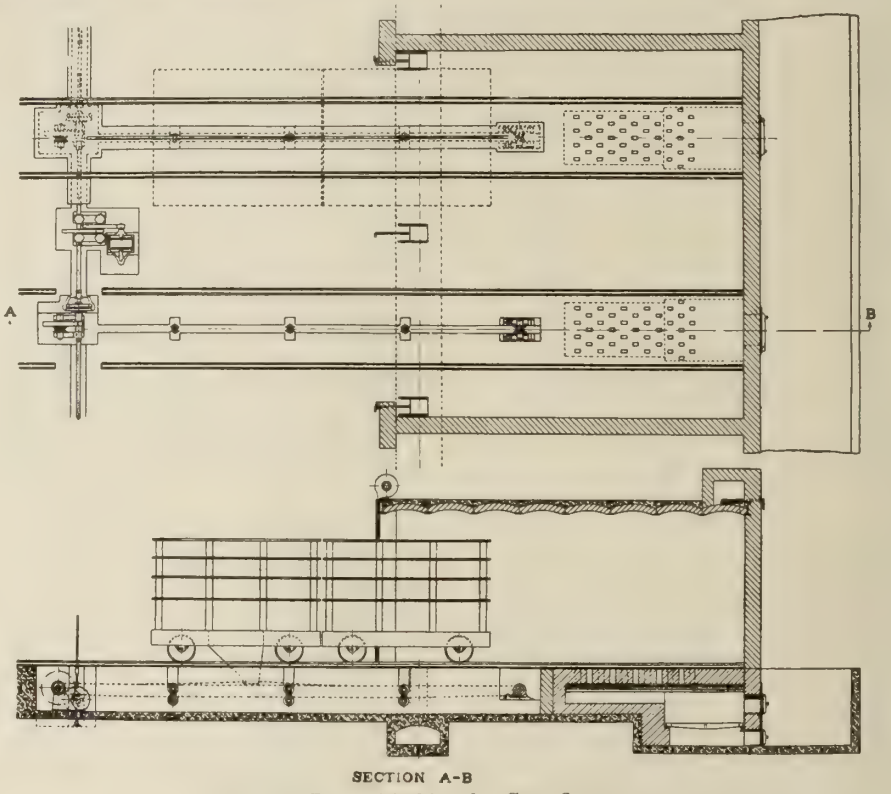
The pulling of metal as it passed from the fluid to the solid state was only briefly referred to, and illustrated by a few instances occurring in simple shapes usually cast in chill moulds; but more attention was paid to the manner in which castings of varying cross-section might bring themselves to an untimely end during cooling from a red heat to atmospheric temperatures. Alloy steels appeared to be very tricky in this respect, which accounted to some extent for the unwillingness of many manufacturers to utilize them for sand castings. It would appear, however, that the difficulties were of such a kind as could be overcome by intelligent care and close observation.—T. E. S.

ELECTRIC PULLER MACHINES FOR CORE OVENS.

THE accompanying illustrations show plan and sectional elevation of a large core oven equipped with an electrically operated machine recently put on the market by the Whiting Foundry Equipment Co., Harvey, Ill., for hauling cars in and out of core ovens. It does away entirely with the necessity for snatch block and tackle operated by overhead crane or laboring gang, and eliminates the disagreeable and irksome task of hooking on to cars in a hot oven or pinching them out.

The apparatus consists of chain pocket wheels and gearing mounted on heavy cast iron bearing brackets securely bolted to suitable foundations in the vertical plane of the tracks for core oven cars. An endless forged chain passes over pocket wheels, being carried by idlers located in a slot below the level of track and attached to an arm extending from the car into the slot. One of these mechanisms is furnished for each track in the battery of ovens. Power is applied by reversible electric motor, using either alternating or direct current through gearing to driving shaft. Each pulling mechanism is controlled by independent friction clutch.

All operating mechanisms are located below floor level in concrete pits, which are covered by floor plates to protect apparatus and prevent accidents. The arrangement may be applied to gas or oil-fired ovens, as well as to the coke oven shown. Also, by modifying the construction somewhat, installation may be made in existing ovens. The location of machines in front of ovens is preferred, but if necessary they may be set in the rear.



SECTION A-B

Electric Puller Machine for Core Ovens.

STEEL WORKS MUST SMOKE.

In an address before the Sheffield Electro-Metallurgical Society Prof. J. O. Arnold took occasion to censure the smoke-abatement movement and to point out that without smoke, steel is impossible. So far as health is concerned, he said, the most mischief is caused by the household smoke, yet it is usually ignored by the smoke inspectors. Strange as it may seem, some medical men have recently taken to recommending the smoky parts of Sheffield for sufferers from asthma. Prof. Arnold asserts that in steel metallurgy, smoke is absolutely necessary. Any operation that removes the carbon will produce poor steel. If a smokeless flame is used, all the carbon is burnt out and the surface of the steel is made rotten. Most municipal authorities realize that smoke is essential to the manufacture of good steel and exempt metallurgical furnaces, but the question of mixed stacks is continually coming up to the annoyance of manufacturers.

MUST BUY IN CANADA.

The Canadian government will hereafter require all materials used for railways subsidized by parliament to be purchased in Canada. An understanding to that effect at present exists, but complaints have been made that it is frequently disregarded, especially in the west. A specific clause providing for the purchase of all material in Canada will in future be inserted in all subsidiary contracts.

The Plant of Harland & Wolff, Queen's Island, Belfast

By Lagan

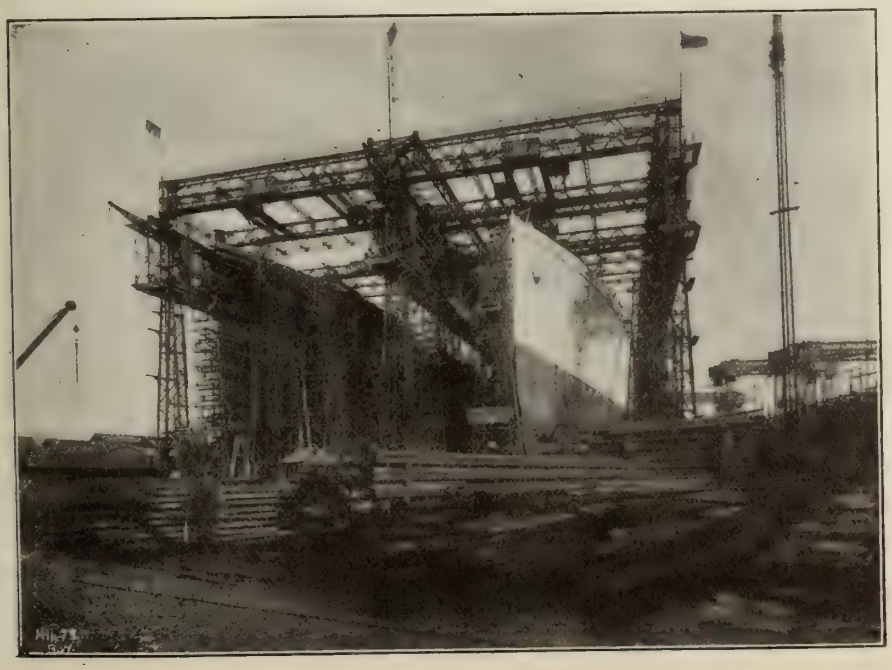
This firm's world-wide reputation and achievements in shipbuilding and marine engineering are known and discussed by men in every section and department of the profession; therefore, the accompanying brief description of the plant and equipment, wherewith the superlative degree of performance has been attained, should contribute to the instruction and education of all classes of our readers.

COMPARATIVELY speaking, the firm of Harland & Wolff is not an old one; but the fact that it has, within a period of little over half a century, risen from being an insignificant establishment covering but a few acres and employing a couple of hundred men, to the position of the finest shipbuilding and engineering works in the world, marks its progress as nothing less than phenomenal. The ground now occupied is upwards of 120 acres, while between 14,000 and 15,000 hands are employed.

Harland & Wolff first began to make history in shipbuilding by the construction of the early Bibby liners, which were a complete departure in the matter of proportions from previous practice; some of these vessels being 10-11 beams to length. A few years later began their connection with the White Star Company, the building of the first Oceanic, pioneer steamer of that line, marking another innovation; the vessel being the first in the Atlantic trade to have passenger accommodation amidships. Since then, they have rarely for any great length of time been without a White Star boat on the stocks. Amongst many notable vessels built by them for this company may be mentioned the Teutonic and Majestic—the great fliers of their day. Following them, came the leviathans, Oceanic (the second), Celtic, Cedric, Baltic and Adriatic; which, in turn, have been easily surpassed by the

Floating Crane.

46,000-tonners, Olympic and Titanic. These, again, are to be eclipsed in point of size by a steamer presently building at Queen's Island, for Ismay, Imrie & Co.



Olympic and Titanic on the Stocks.

Large Tonnage Vessels a Feature.

Lord Pirrie has always been a strong advocate of the big ship, and the large number of leviathans put in the water from the Queen's Island stocks affords striking evidence of shipowners' concurrence in his views on naval architecture. Within the past twenty years or so, close on 60 of the vessels launched there, have been over 10,000 gross tonnage each. Of these a considerable number exceed 15,000 and 8 have a gross tonnage of over 20,000 each; two—the Olympic and Titanic—being vessels of 46,000 tons gross. The firm holds the record output for 1911, a distinction attained also in previous years. A shipbuilding company occupying such a position must, therefore, necessarily have extensive premises equipped with the most up-to-date machinery for expeditious and economical production, and in this respect, the Queen's Island shipyards and engineering works are unsurpassed.

Yard Equipment.

At the south end of the yard two of the slips are served by a double-armed cantilever crane travelling on a high gantry which extends between, and the whole length of these ways; while at the north end there are the huge gantries under which the Olympic and her sister-ship Titanic were constructed. On these are numerous electric traveling cranes for light and heavy lifts, capable of lifting and depositing material over the entire area of the two slips. The aggregate brake h.p. of the motors used for driving the cranes, riveting plant, etc., carried on these gantries is over 1,400. Then, there is the monster floating crane which is used for lifting engines and boilers on board. This crane was tested to a load of 200 tons.

Turning now to the shops, in the platers' sheds we find here the same evidence of up-to-dateness; the tools—plate bending rolls, punching and shearing machines, etc.—being of the very latest types, and all driven by electricity generated in a central station which for size and contents is hard to surpass anywhere. In the various other departments we find the same principles of perfect equipment and organization carried out. The buildings are all extensive, lofty, well lighted, and replete throughout with the latest products of

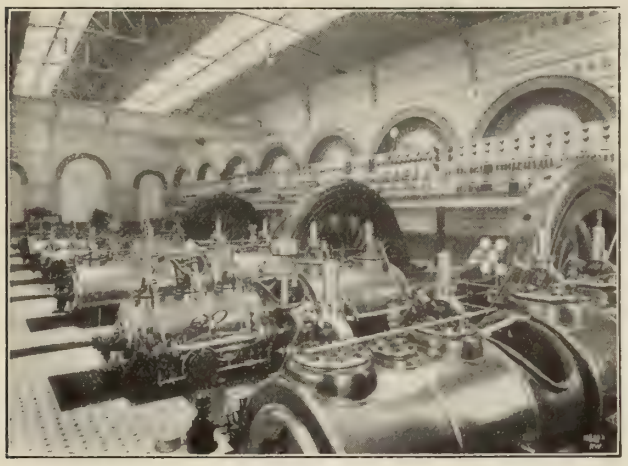
the brains of those whose attention is given to the labor-saving problem.

Erecting and Heavy Machine Shop.

The total length of the recently built erecting and heavy machine shop is 750 feet, the total breadth is 89 feet and the total height is 77 feet 6 inches. The design, generally, provides for a construction in which rigidity and stiffness, as well as strength, have been given careful consideration. The roof is entirely covered with glass except for the ventilator hood; the glazing being of rough cast plate 1-4 inch thick, laid in putty, and so arranged as to give the maximum amount of light possible. Large windows are fitted along one side and smaller ones at the top near the roof. One end, opening on Queen's Road is built of brick.

A gangway has been fitted inside the shop to give access to the crane girders, and another one outside gives access to the roof; both being protected by handrailing. Three overhead electric travelling cranes are provided, two of them capable of lifting together 200 tons and the third 25 tons. The floor is laid with Jarrah wood blocks, supplied and laid down by the Acme Flooring & Wood Paving Co. on a foundation of 9 inches of concrete.

A line of rails connects with the Harbor Tramway in Queen's Road, to a heavy turntable near the centre of the shop, which in turn connects with the iron foundry. Irish Standard gauge rails at the upper end of the shop communicate with the brass foundry. Narrow gauge tramways communicate with all shops.



Electric Power Station.

A bay of the machine shop.

Machine Tool Features.

The following is a short description of the larger and most important machine tools which have been installed:—

One universal double horizontal boring, drilling, tapping, studding and milling machine by Thos. Shanks & Co.

The slide bed of this machine is strongly constructed and is 26 ft. long by 5 ft. broad. Mounted on the slide bed are two strong box section vertical columns which slide along the bed both by hand and power, the power movement being through an independent motion shaft, driven by an auxiliary motor of 12 B. H. P. The columns, which have a horizontal traverse, give a maximum range of 20 ft. between centres of spindles. The spindle, which is carried on a slide mounted on the vertical columns, has a vertical range of 13 ft. The main drive is from two separate and independent variable speed, shunt-wound, 18 h.p. motors—one mounted on each column and sliding along the bed with it, connected with the necessary gear so that no long driving shafts are in the bed, while the drive over each spindle is entirely free and independent of the other, both for speed and direction. The spindles are 4 3-4 inches diameter, with a traverse of 36 inches. The work table which is bolted to the sliding bed is 20 ft. by 10 ft.

One heavy, quadruple geared, double bed, turbine lathe by Shanks & Co., for turning turbine rotors.

This has a double sliding bed of great width and depth and of special section to resist strains. The fast headstock of massive design has a forged steel spindle with large diameter in the front journal, also thrust rings for end pressure. The arrangement of gearing is Shank's latest improved plan with quadruple and double purchase driven by a direct connected, shunt wound, variable speed 60 b.h.p. motor. This new drive is of the simplest character, ensures silent run-

A portion of the boiler shop.

New addition to machine and erecting shops.

ning and reduces torsion through the shafts, at a minimum expenditure of power. The saddles are 4 in number, specially constructed for heavy strains, and have independent power traverse either way through the racks. This lathe is 100 inches centres, will admit 50 feet between same and will swing over the saddle 14 ft. 11 inches, and over the shears 16 ft. 9 inches. The gross weight is about 174 tons.

One vertical and horizontal planing machine for machining turbine casings, engine bedplates and large general work of all kinds:—

The foundation bed is of very strong design. The work table, a small part of which is cast in the foundation bed, has its main portion securely checked into the foundation bed, and firmly secured there with bolts. The vertical bed is in two castings of specially strong and rigid design. The travelling standard is of large box section strongly ribbed and capable of withstanding heavy cuts without spring. The machine is driven by a 30 h.p. motor direct-connected to the machine by the necessary gear. A platform is fitted to the traveling standard and also to the saddle thereon, so that the attendant may constantly follow the surface being machined.

One patent steam turbine casing boring machine:—

This consists of three parts:—(a) the machine proper; (b) two heavy double stays; and (c) baseplate for supporting the work. The machine includes a wide slide bed with two driving shafts, and in the middle a guide screw; while on the outside it is provided with a planed tee groove for facilitating the setting of the column when grooving. A strong box section column slides upon this bed, with quick power reversing speed, and two independent systems of variable feed. The headstock saddle is balanced and has power vertical adjustment to obtain the exact height from work plate required. The drive is from a 40 b.h.p., shunt-wound, variable speed motor, 300 to 900 r.p.m. The motor is placed at the end of the bed and connected to the driving shafts in the slide bed by the necessary cut wheels; giving 40 speeds through worm wheel slow drive, and 40 speeds through the bevel gear quick drive. These are so arranged that the one drive must be clear and disengaged before the other can be engaged. Two heavy double stays are fitted for carrying the boring bar. The baseplate for supporting the work and the boring stays consists of four castings planed on the joints, securely checked and bolted together. The principal dimensions of this machine are:—width of slide bed, 8 ft. 6 inches; traverse of column, 9 ft. 6 inches; largest diameter to bore, 17 ft.; maximum height work plate to centre of spindle, 9 ft. 6 inches; diameter of worm wheel, 8 ft; and size of baseplate, 45 ft. 10 inches by 16 ft. This machine is also by Messrs. Shanks.

One vertical cylinder boring machine with 16 inches diameter boring bar, capable of boring cylinders 112 inches diameter by 75 inches stroke.

One vertical cylinder boring machine with 15 and 11 inch boring bars, capable of boring cylinders 80 inches diameter by 60 inches stroke.

Two surface tables, each 20 ft. x 15 ft. x 18 inches deep, are placed 3 ft. apart, so that they can be used either singly, or if required for larger castings or shafts, the two tables can be used together.

A large bed has been made for erecting engines. It is 136 ft long x 50 ft. wide over all, and has nine rows of concrete blocks, 2 ft. square; the whole length of the bed being supported by 176 pitch pine piles 13 inches square by 30 ft. long. On this bed five or six sets of marine engines can be erected simultaneously, according to their sizes.

White Star Line Steamship "Titanic," Which Foundered in Mid-Atlantic on the Early Morning of April 15, 1912.

Allied Accessory Equipment.

Harland & Wolff have from time to time added various allied branches of the shipbuilding and engineering industries to their works. They have had from the first their own iron and brass foundries; while some years ago they built a fine coppersmiths' shop, and about the same time took up electrical engineering for the fitting-out of their vessels with electric light installations. Now they are about to commence the making of refrigerating plants, which, hitherto, have been supplied them by firms who make a specialty of this class of work. They have for many years made the great bulk of auxiliary machinery required on shipboard, and non-conducting material for boiler covering is manufactured and applied by their own staff.

Management Features.

Throughout the entire establishment—shipyard and engine works—it may be said that a weeding-out is in constant process; Lord Pirrie's dictum in this respect being to the effect that as soon as an improved type of any class of machine is brought out, the old tool must go. The finest works in the world, however, in any business, will not make for economical and efficient production if proper management is lacking. Harland & Wolff's operations are conducted by an efficient staff working under capable management, and above all, there is Lord Pirrie's guiding hand.

Steam Heating and Isolated Power Plant Cost

American Engine Co. Report.

There is here discussed a variety of conditions likely to be met in the realm of Isolated Plant Power with Steam Heating as its basis. Climatic conditions in Canada call for a more or less protracted season during which steam heating is necessary and in the development of our manufactures, a large degree of isolation often becomes necessary, therefore, the typical examples and figures given, relative to costs involved, will be found interesting and valuable.

WHERE steam heating is required, electric power may be generated as a by-product of the heating plant, at a cost of less than 2 cents per kilowatt-hour in the majority of cases. The reasons for this low cost of generation may be summarized as follows:

(1)—The fixed costs, which go to make up a large share of the cost of power, are chargeable only against the additional investment for the plant by which electric power is generated, over and above the investment for the low pressure steam heating plant.

(2) — The coal cost chargeable against electric power is reduced, during those periods when the exhaust steam is used for heating, to a small percentage of the coal consumed, representing that part of the heat in the steam which is lost between the high pressure boiler and the heating system.

(3)—The labor charge comprises only the additional labor required, as compared to a low pressure heating plant. Furthermore, by reason of the additional labor, which is of a higher grade, greater economy is obtained in fuel consumption, amounting to a saving in coal of 5 to 15 per cent., which in a plant of fair size will pay the wages of an engineer.

(4)—While the charges for oil, waste, repairs and miscellaneous items are incurred entirely through the installation of the engine and generator, they amount to a small proportion of the total expense.

Every isolated plant with exhaust steam heating must be considered as a separate problem, because of the wide variation in load, cost of coal, water, labor, etc. The following case, which may be presented as a typical one, will serve to outline the calculation whereby the cost of power may be determined, and, secondly, to indicate the influence on the cost per kilowatt-hour of the three most important factors—the fixed charges, the price of coal and the amount of exhaust steam used for heating.

Fixed Charges.

An industrial plant operating 3,000 hours per year, with an average load of 200 K.W., will be assumed. Two 100-K.W. and one 50-K.W. engine-driven dynamos, installed with suitable piping and appurtenances, will cost about $11,000.

Two 200-H.P. boilers would be required; however, the total cost of these boilers would not be chargeable against power, since boilers would also be required for the low pressure heating plant. The cost per horse-power of low pressure boilers, grates, stack, etc., is about the same as a similar high-pressure equipment. Because heat is lost and consumed between the high pressure boiler and the heating system, a somewhat greater boiler capacity must be installed when power is to be generated, and as the exhaust from an engine contains from 80 to 90 per cent. of the heat given to it by the boiler, an increase of the latter's capacity of 25 per cent. over the low pressure equipment will take care of this item and also any additional cost of a high pressure boiler as compared to a low pressure equipment.

At $18.75 per horsepower, including boiler, grates, stack setting, piping and labor of installation, the additional boiler cost is $1,500. This additional boiler cost will vary; in fact, in plants already equipped with low pressure boilers, it will pay to replace the equipment with high pressure boilers and utilize exhaust steam for heating.

The two largest items of additional first cost, totalling $12,500, have been considered. It might, of course, be profitable to install other apparatus in a plant of this character, as for instance a feed-water heater, but as that piece of apparatus should pay for itself out of the coal saved, it will not be considered under the items of additional first cost.

Of the total additional cost of $12,500, a certain fixed percentage must be charged annually against the cost of power. The fixed charge may be set down as follows: Interest, 5 per cent.; depreciation at 5 per cent.; insurance, real estate, upkeep, obsolescence, 5 per cent.; total, 15 per cent., or $1,875, which is the fixed charge per year against the additional investment for apparatus to generate power as a by-product of the heating system. The cost for additional labor may be taken as one man at $800 per year, while repairs, oil, waste, packing, etc., may be set down as $250, making a total of $1,050.

Coal.

The coal chargeable against power comprises the coal equivalent of the heat lost between the high pressure boiler and the heating system when the heating season is in use. When no heating

No. of months of exhaust steam heating.

Fig. 1—Cost of power per K.W. hour for various prices of coal and periods of heating with exhaust steam.

is being done, all of the coal burned under the boiler is chargeable against power. The cost for coal will, therefore, depend upon (a) the steam consumption of the engines per K.W.-hour; (b) the efficiency of the boiler; (c) the cost of coal; (d) the percentage of the total amount of steam generated which is used by the heating system.

(a)—The steam consumption of an American-Ball angle compound engine is 26 lb. per horsepower-hour (non-condensing), or 40 lbs. per kilowatt-hour. In order to be on the safe side and to take care of the effect of reduced and fluctuating loads on steam consumption, assume 60 lbs. of steam per kilowatt-hour.

(b)—Assume a boiler efficiency of 60 per cent., or about 8 lbs. of steam per pound of coal.

(c and d)—The cost of coal and the proportion of the total steam generated which is used in the heating system, are both variable.

In the Table given herewith, the cost of coal ranges from $1 to $5. The amount of steam used in the heating system is taken care of by considering it as the number of months of the year when all the exhaust steam is used for heating.

Strictly speaking, at the beginning and end of the heating season, there are periods when only a moderate amount of heating is required and only a portion of the steam exhausted by the engines is utilized. This decrease in heating load may be taken care of by assuming a shorter heating season. For example, suppose that for four months during the winter, all the exhaust steam was used in the heating season and that for one and a half months before and after this season the amount of steam used in the heating system varied from zero to full capacity. It would then be quite accurate to assume that the heating season of 7 months would be equivalent so far as amount of steam used for heating, to a season of 5½ months in which the heating load was always equivalent to the full exhaust of the engine.

Water.

An average price for water is 10 cents per 1,000 gallons. During the heating season it is reckoned that only 80 per cent. of the water is returned to the boiler. During other periods all the water is lost. It should be noted that it is assumed that in a low pressure heating system all the water is returned to the boiler, that is, there is no loss, and in setting down the additional cost for water when power is produced as a by-product, it is assumed that condensation in high pressure steam piping, condensation in the engine, etc., results in a 20 per cent. loss during the heating season and when the steam is exhausted to atmosphere, a 100 per cent. loss. With the fixed costs, labor cost, already given, and calculating the coal and water charges for given conditions, the table and charts shown were obtained. The following example will serve to explain in detail the method of obtaining these figures.

Example.—Assume the heating season equivalent to six months of full load steam heating, during which all the exhaust is used. During this period the coal chargeable against power is the equivalent of the steam and heat lost between the high pressure boiler and the heating system. Assume, also, that 20 per cent. of the heat of the steam is lost in this manner. The other factors entering into the coal cost have already been given—load 200 K.W.; steam consumption 60 lbs. of steam per K.W.-hour; coal consumption of 1 lb. of coal per 8 lb. of steam, and hours per year, 3,000. With coal at $4.00 per ton, the cost of coal during the 6 months heating period is $900.

The part of the year when there is no exhaust steam heating, and those parts of the year when only part of the exhaust steam is used for heating, are equivalent to six months of straight non-condensing operation. The cost of coal is therefore $4,500. To this coal cost must be added the cost for water at 10 cents per 1,000 gallons. During the heating season, the heating sytem returns 80 per cent. of the boiler feed and the cost for water is $43.20.

COST OF POWER IN CENTS PER K.W.-HR. IN A TYPICAL ISOLATED PLANT; AVERAGE LOAD, 200 K.W.

Months of Exhaust Steam Heating	—Price of Coal, Dollars Per Ton—					
	$0	$1	$2	$3	$4	$5
2	.550	.880	1.200	1.525	1.850	2.175
4	.540	.820	1.090	1.365	1.640	1.915
6	.531	.755	.983	1.205	1.431	1.656
8	.521	.700	.871	1.046	1.221	1.396

For the other six months the cost for water is $216.

We may now set down the total charges for generating power at the rate of 200 K.W. for 3,000 hours a year, as follows:

Fixed charges	$1,875 00
Labor, oil and misc.	1,050 00
Coal	4,500 00
	900 00
Water	216 00
	43 00
Total	$8,584 00

During the year there is developed 3,000×200=600,000 K.W.-hours, giving a cost per K.W.-hour of $8,584÷500,000 =1.431 cents per K.W. hour. In the same manner it is found that when the heating season is equivalent to only two months of full-load heating, the cost per K.W.-hour is 1.85 cents. For the same conditions when the price of coal is $5.00 instead of $4.00, the cost per K.W.-hour is 2.175 cents, and in this way the table shown was compiled.

Charts.

From these data the charts of Figs. 1 and 2 were prepared. In Fig. 1 the cost of power in cents per K.W.-hour (average over the whole year) is plotted against the number of months that exhaust steam is used for heating, each line representing a different price of coal. With this chart in hand, we can study the influence of coal cost, length of heating periods, the influence of first cost, and also of percentage of that cost which should be charged off per year in order to take care of interest, depreciation, etc.

The chart may also be used to consider the cost of power in a plant where a low pressure boiler is already installed and must be replaced. The additional first cost of the high pressure boiler over and above the low pressure boiler, taking into account the fact that a boiler of higher capacity would be required, was assumed at $1,500. Assume that an entire new boiler would be needed costing $7,500. This would increase the additional first cost of the plant by $6,000 and the additional yearly charges by $900, making the total fixed charge $2,775. For 600,000 K.W.-hours per year, this would increase the fixed charge per K.W.-hour from 0.312 cent to 0.462 cent. The influence of this additional charge of 0.15 cent upon the cost of power with $4 coal, and when three months' exhaust steam heating is used, is therefore an increase from 1.75 cents to 1.90 cents per K.W. hour.

In the chart Fig. 2, the cost per K.W.-hour is plotted against the cost of coal in dollars per ton, and each line represents the cost for different lengths of heating periods. This chart is useful for investigating the effect of the price of coal and also the comparative effect of length of heating season and price of coal. For instance, the cost per K.W.-hour is practically the same, for an eight months' solid heating season with $4 coal, as it is with a two months' heating season with $2 coal. On reference to this chart, it will be noted that the costs exclusive of coal and water are considered separately—being plotted against load factor.

A load of 200 K.W. for 3,000 hours per year is considered as 100 per cent. load factor (although the plant capacity is 250 K.W.), At 100 per cent. the fixed charges, labor, etc., per K.W.-hour are 0.488 cent. Similarly at 50 per cent. load factor the cost per K.W.-hour exclusive of coal and water is 0.976 cent. By similar calculations, the complete curve is plotted, which may be used in connection with the curves at the right in order to study the cost of power un-

der various conditions. Suppose, for instance, that the load factor is 50 per cent., then the ordinate (a)—10.98 cent fixed charges, labor, etc.; if the coal cost is $4 a ton and the number of months of exhaust steam heating is 4, then the coal and water cost per K.W.-hour is given by (b) as 1.17 cents and the total cost of power per K.W. hour is a×b= 2.15 cents.—From a report by the American Engine Co., Bound Brook, N. J., in Industrial Engineering.

"ECONOMY" 16-INCH DOUBLE BACK-GEARED ENGINE LATHE.

THIS lathe conforms strictly to the new demands and conditions of modern shop practice. It is rigid and powerful, representing the highest standard of workmanship and design, while its special features are applicable to a wide range of work; making it, therefore, a most convenient and practical tool.

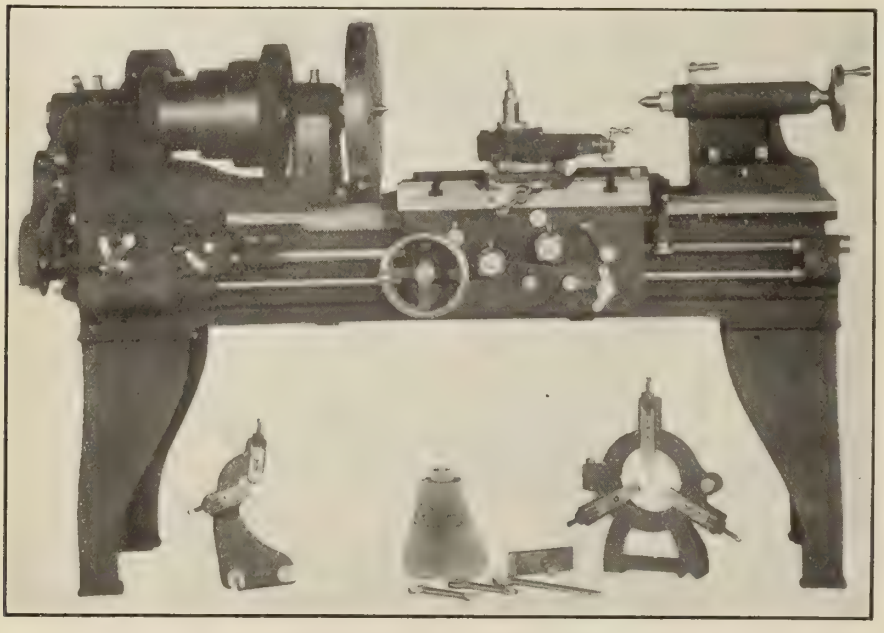
The bed is of deep section, with wide cross braces, which, together with a thorough distribution of metal, eliminates all vibration under heavy duty. The headstock is massive and firmly bolted to bed; the bearings, exceptionally large, are of the best quality babbitt, and the spindle of high carbon steel, accurately ground, has a 1½ inch hole its full length, permitting draw-in collets up to 7-8 inch capacity.

The tailstock, of the off-set type, allows the compound rest to set parallel to the bed, and is provided with set-over for turning tapers. Double clamping bolts ensure the tailstock being kept in position without slipping. The carriage is especially heavy with extra wide bridge which permits a heavy cut without chatter. It has a bearing of 26¼ inches on the ways, and is provided with self-oiling felt wipers. The thread cutting indicator, which can be disengaged when not in use, will be found a valuable feature when cutting long threads. The apron is of heavy design, with double bearing for all shafts; this is a very essential feature for heavy duty lathes. The gears are of wide face and coarse pitch. and, being cut from steel, withstand the constant strain without breakage, and with small wear. All feeds are reversed in apron, and interlock with lead screw nut; making it impossible to engage feeds and lead screw at the same time.

The gear box is designed to combine strength with simplicity. Three quick changes of feed are obtained for each change of gearing through sliding steel gears and hardened steel clutches, which give a powerful drive and an unlimited range of feed for all classes of work. This gear box simplifies thread cutting; all pitches being obtained without the troublesome compounding of gears, which has always been a great disadvantage of change gear machines.

The double friction countershaft has pulleys 12-inch diameter for 4-inch belt. The speeds are forward, 200; backward, 250, r.p.m. The regular equipment includes steady and follow rests, large and small face plates, full set of change gears, countershaft, and wrenches; while at extra cost, draw-in attachment and collets, taper attachment, turret on carriage and turret on shears with or without power feed, are furnished at extra cost.

The lathe is manufactured by the Rockford Lathe and Drill Co., Rockford, Ill.



Rockford 16-inch Economy Lathe.

R. J. LEVY A TITANIC VICTIM.

Mr. R. J. Levy, manufacturer of oxygen and proprietor of various oxy-acetylene welding and cutting equipments at Montreal, is believed to have lost his life through the disaster to the White

THE LATE R. J. LEVY.

Star steamship Titanic. Mr. Levy, who is also an expert chemist, left Montreal early in March of this year on a business trip to London and Paris. He wrote his family, stating that he was returning by that vessel as a second-cabin passenger. Mr. Levy was 35 years of age, and in a brief space of time had become prominent in the development and progress of oxy-acetylene cutting and welding throughout the Dominion.

AMERICAN FOUNDRYMEN'S CONVENTION.

The date of the 1912 convention of the American Foundrymen's Association, has been definitely set for the week of September 23. As previously announced, Buffalo, N. Y., is the place of meeting, and following the practice of former years, the Foundry and Machine Co. Exhibition, the American Institute of Metals and the Associated Foundry Foremen meetings will be held there concurrently.

The A. F. A. have selected the hotel Statler as their headquarters; the F. and M. E., the Hotel Lafayette, and the A. I. M. the Hotel Iroquois.

Mr. Valentine Boyd, recently on the staff of the Canadian General Electric Co., Toronto, has joined the staff of the Canada Machinery Corporation, Galt, as assistant to the general manager.

Industrial and Construction News

FOUNDRY AND MACHINE SHOP.

Craik, Sask.—There is now under construction here a machine shop which will be up-to-date in every particular. The building will be forty feet wide and sixty feet long; one end will contain the forge, while the other will be used as a garage. Harvie Hawes from Toronto is the machinist.

Woodstock, Ont.—City Clerk Morrison has declared the by-law carried, granting aid to the Woodstock Automobile Company. Thus, the activity of the company will eventually follow.

Saskatoon, Sask.—J. A. McMillan and T. W. Renwick have formed a company capitalized at $50.000 and to be known as the Saskatchewan Motor Works Co., Ltd.

Ingersoll, Ont.—The ratepayers ratified the by-law to expend $125,000 to cover the cost of buying the plant of the Ingersoll Waterworks Company.

Walkerton, Ont.—The voters recently passed a by-law to raise $10,000 to aid the manufacturing of harness and vehicles.

St. Catharines, Ont.—The Reo Motor Car Company of Canada are contemplating enlarging their present plant in this city to over double its present capacity of 600 cars per annum.

Sumas, B. C.—The result of a conference recently held between the officials of the International Lime Company of Kendale and the business men of Sumas was that it was decided to move their headquarters from Seattle to Sumas. This change is owing to the Kendale plant not being up to the demand and it is the intention to increase the output of the plant immediately.

Okotoks, Alta.—Within a month or two, work will be started on the building of a railway to the properties of the Alberta and Canada Iron syndicate, 25 miles west of here. When the railway is completed, a mill will be erected and iron will be mined. The whole project will cost about $5,000,000. P. Burns is behind the venture.

Ipswich, B.C.—It has been announced that a factory for the production of Diesel engines is to be established at this place and will cost $240,000. The Diesel Company have obtained an option on a site belonging to the Ipswich corporation.

London, Ont.—The Street Railway Company, Manager C. B. King, will equip a car repairing plant and will purchase all necessary machinery. The cost will be $7,000.

Port Colborne, Ont.—A by-law was passed recently to grant concessions for a steel and iron smelter plant to cost $1,000,000 for The Union Furnace Co., Buffalo, N.Y. The subsidiary owners are Canadian Furnace Co. of Port Colborne.

Chatham, Ont.—The recent by-law, providing for a machine plant to cost $100,000 for the St. Mary's Machine Co., of Ohio, of whom D. Anderson is manager, has been carried. The company will occupy the premises vacated by the Swift Motor Car Co. A new equipment will be required and Mr. Anderson will superintend the installation which will commence at once.

Galt, Ont.—A new plant for the manufacture of lathes, planers and other machine tools will locate here. Mr. Wm. Preston is looking after the new plant. A complete new equipment of machinery will be required.

Guelph, Ont.—C. J. Furber & Co., will equip a new factory for the manufacture of metal weather stripping screens and ventilating appliances. New machinery and equipment will be required.

Hamilton, Ont.—A construction plant to cost $200,000 is under consideration by the American Locomotive Co., 30 Church St., New York City.

Owen Sound, Ont.—A new grain elevator to replace the old elevator recently destroyed by fire is being contemplated by James Playfair of Midland. Complete loading and unloading facilities will be installed. The cost will be about $100,000.

London, Ont.—Manager C. B. King, of the street railway, states the company will equip a car repairing plant for which all necessary machinery will be purchased. The cost will be about $7,000.

Brantford, Ont.—A report states that the American Radiator Co. will erect an important addition to their plant. The extension will be about 750 feet in length.

Welland, Ont.—The management of the Welland Machine and Foundry Co. will erect a new foundry, a paint shop and storehouse and will install one or more travelling cranes.

Regina, Sask.—The management of the Cockshutt Plow Company have let the contract for

the erection of a new factory in this city. It will consist of three stories and a basement constructed on the property owned by the company in Block 77 with a frontage of 150 feet on Broad Street, and 100 feet on Fifth Avenue. The plans include two large-sized heavy capacity freight elevators. The total cost is estimated in the neighborhood of $120,000.

Vancouver, B.C.—The Standard Iron Works, of Vancouver, B. C., began business on March 15. The works are conveniently located on the water front, with the railroad on one side and a wharf on the other. A general boiler, tank and sheet iron business will be carried on. The shop equipment is of the very latest design, and was installed with the idea of handling large jobs. The young men behind this enterprise are thoroughly equipped, and we predict a bright future for them.

New Glasgow, N.S.—The Canadian Bridge Company have recently purchased a large stock of shares of the Wm. P. McNeil Company, New Glasgow, Nova Scotia. Mr. K. W. Bash has been appointed vice-president and engineer, and Mr. W. McNeil is the president and manager of the new company. Extensive improvements were made to the plant during the past year, resulting in well-equipped works for the manufacture of structural steelwork and further improvements are anticipated in the near future. Other than the changes noted above, the policy of the company will remain intact.

New Westminster, B.C.—The Schaake Machine Works Co. are about to build a new and much larger plant here.

MUNICIPAL.

Ormstown, Que.—A by-law will shortly be submitted for ratification to raise $52,000 for waterworks and sewers system.

Calgary, Alta.—On May 3rd the burgesses will vote on a by-law to raise $300,000 for the construction of a drainage system.

Weyburn, Sask.—The burgesses will vote on a by-law to authorize the expenditure of $25,000 for a sewerage system.

Melville, Sask.—Among the several by-laws about to be submitted to the burgesses for ratification is one calling for the raising of $3,300 for a power house.

Dunnville, Ont.—The council is contemplating submitting a by-law to authorize the borrowing of $10,000 as a bonus to the Sewsure Manufacturing Company.

Vernon, B.C.—Concerning the reported purchase of the Coteau Power Company by Mackenzie and Mann (C.N.R.), and the burning of the power plant in this city, it is now reported to be unlikely that the city will build again, but will arrange with the Coteau Power Company for a supply of light and power.

Comber, Ont.—The ratepayers of the Township of Rochester are contemplating voting on a by-law to raise $1,140 to cover cost of drainage work.

New Westminster, B.C.—A by-law will soon be submitted to authorize the raising of $40,000 for waterworks.

Windsor, N.S.—The burgesses will shortly vote on a by-law to raise $75,000 for sewerage system.

St. Catharines, Ont.—The burgesses will probably be asked to vote on by-law to raise $40,000 re construction of new sewers.

Montreal, Que.—The ratepayers will shortly have the opportunity of authorizing the expenditure of $400,000 for new sewers, sidewalks and water mains.

Vernon, B.C.—The burgesses will be called upon to vote on a by-law to raise $40,000 for waterworks extension; also a by-law to raise $7,500 for municipal building.

New Westminster, B.C.—The ratepayers have voted $400,000 for road and waterworks extensions and city enterprises.

Saskatoon, Sask.—A by-law is being prepared calling for the borrowing of $220,000 to cover cost of abattoir system.

Kelowna, B.C.—A by-law will soon be submitted to ratepayers to sanction the raising of $7,000 for water system.

Township of Tilbury West, Ont.—A by-law is about to be submitted to the ratepayers for the raising of $3,914.25 re cost of drainage in the townships of Rochester and Tilbury North.

Point Grey, B.C.—It is probable a by-law will soon be submitted to the ratepayers to raise $187,710 re water supply.

Windsor, N.S.—The burgesses are contemplating voting on a by-law to raise $75,000 for sewerage.

Swift Current, Sask.—The ratepayers will be asked to vote on a by-law to raise $10,000 for publicity work.

Fergus, Ont.—The ratepayers passed a by-law to raise $35,000 for a waterworks system.

St. Catharines, Ont.—A by-law to aid, by fixed assessment, a company being formed by H. B. Stone, of Warren, Pa., a shareholder of the Warren Axe and Tool Company, will be voted on by the ratepayers soon.

W. H. BANFIELD & SONS
TORONTO, ONT.

Toronto, Ont.—The finance committee of the Board of Education has accepted the following tenders:—Duke of Connaught School: masonry and steel work, $53,200, J. Bayfiss and Son; terra cotta, $6,608, Robert Bennett; carpenter work, $22,545, William Williamson; plastering, $5,294, George White; painting, $2,630, J. R. Robinson; roofing and tinsmithing, $2,021, W. E. Dillon and Co.; iron stairs, $4,500, Dominion Ornamental Iron Co.

Regina, Sask.—The following contracts have been awarded by the city council:—Seventh Avenue trunk sewer, $41,133.70, Canadian Lock Joint Pipe Company; Wascana Valley trunk sewer, No. 1, $29,631.04, American Sewer Pipe Company; Wascana Valley trunk sewer, No. 2, $20,585.20, Broley and Dickson, of Fernie, B.C.

ELECTRICAL.

Regina, Sask.—The burgesses voted on several by-laws recently, and among those carried was that to raise $83,000 for an electric light and power system.

Pentieton, B.C.—The ratepayers will vote soon on a by-law to raise $20,000 for electric light extensions.

Fort Frances, Ont.—The ratepayers voted in favor of a by-law to grant a bonus of $25,000 to the Ontario and Minnesota Power Co.

Brantford, Ont.—The city council has been advised to submit a by-law involving an outlay of $109,000 for the installation of a hydro-electric system.

Brockville, Ont.—A by-law empowering the town council to enter into an agreement with the Hydro-Electric Commission for a supply of power for the town was carried by a good majority when submitted recently.

Vernon, B.C.—The ratepayers will shortly vote on a by-law to raise $40,000 to cover the cost of the electric lighting system about to be installed.

St. Mary's, Ont.—The ratepayers propose to spend $5,000 for electric power purposes.

New Westminster, B.C.—Among by-laws voted upon recently and passed was one to raise $25,000 for electric lighting purposes.

PLANING MILL AND SAW MILL.

Midland, Ont.—A by-law was passed by the ratepayers recently granting a loan of $25,000 to Benson & Bray for the erection of a planing mill.

Chicken Lake, B.C.—A sawmill is about to be installed at this place, capacity 15,000 feet daily.

Robert Marr, of Princeton, B.C., is erecting a sawmill to cut 35,000 daily.

New Westminster, B.C.—The Schaake Machine Works, of this place, are about to build a new and much larger plant here.

Vancouver, B.C.—The Britannia Mines Co. will in the near future install a new hydro-electric plant. It is said this plant will operate under the highest head to date in Canada, at 1,800 feet.

Vernon, B.C.—This town is negotiating with the Couteau Power Company for a supply of electric power.

Wheatley, Ont.—It is reported that complete new machinery for an electric light plant will be installed.

Wetaskiwin, Ont.—The by-laws to expend $39,000 on waterworks and power plant both carried.

New Hamburg, Ont.—Electors will vote on a by-law to loan $20,000 to an industry which will manufacture electrical supplies here.

North Battleford, Sask.—The proposed addition to the electric light plant will involve an expenditure of about $30,000.

North Battleford, Sask.—Tenders have been called for a 750 h.p. engine and 500 k.w. generator.

Quebec City, P.Q.—The Dorchester Electric Company have announced that they will have a steam plant in operation by the first of November, and that later they will build a hydro-electric plant and keep their steam plant as a reserve.

Thorold, Ont.—The Montrose Paper Company are asking tenders for 36 motors aggregating 900 h.p. and other equipment.

Verdun, Que.—The town council has passed a by-law to provide $229,000 for increased fire protection, extension of water, filtration and electric light plants, and for water mains, sewers and general improvements.
HAMBLIN—C M

BUILDING NOTES.

Fort Frances, Ont.—It is reported that a Winnipeg company is about to build a large departmental store, and that the Hudson Bay Company is behind the movement. The report, however, has not been confirmed.

Montreal, Que.—The new Alexander St. structure to be built this summer will be the largest building in Canada. It will be known as the "Read Building," and will cost about $1,000,000.

Winnipeg, Man.—Stores Commissioner Burbidge, of the Hudson's Bay Company, states that work has begun on the Calgary store, which will cost $1,500,000. A $25,000 garage is also being built. At Yorkton a $50,000

store will be erected this summer. The steel work in the Calgary store has been awarded to the Dominion Bridge Co., Montreal.

Saskatoon, Sask.—Plans are now being prepared by Thompson, Daniel and Colthurst, architects, for a new $150,000 hotel building.

Montreal, Que.—The McGill Property Syndicate obtained a permit to erect an eight-storey office building, to cost $300,000. R. E. Bostrom is architect, and C. E. Deakin builder.

Lethbridge, Alta.—The board of trade announces that a $300,000 hotel will be erected immediately. Messrs. Paul, Falver and J. F. Davis, of Calgary, are behind the enterprise.

Toronto, Ont.—The old Bay Street firehall property has been leased to Norman G. Heyd and A. H. Sarrett. The firehall will be torn down, and in its place a 10-storey office building is to be erected, the cost of which will be about $200,000.

Calgary, Alta.—The contract for the erection of the new King George School was awarded to Jones and Lyttle, at $125,620. The heating and plumbing contract was given to Grant Bros., at $21,850.

Vancouver, B.C.—Plans are completed for the new central building, which is to be erected on Granville St. The building will be 18-storey high, and will contain 54 rooms in all. The property was bought for $400,000.

Fort William, Ont.—It is announced that four 4-storey wholesale houses will be built this year. The promoters are Cameron and Heap; Matthews, Lang Co.; Fife Hardware Co., and Fitzsimmons Fruit Co.

TRADE NOTES.

The Smart-Turner Machine Co. have recently secured the following orders:—The Port Dover Brick & Tile Co., Port Dover, Duplex Pump; The Stouffville Cider and Vinegar Co., Stouffville, Ont., No. 1 Side Suction Centrifugal Pump; J. C. Wilson & Co., Lachute Mills, Que., Simplex Power Vacuum Pump; Capt. R. Gavin Dredge "Industry," Collingwood, Ont., Duplex Packed Piston Pump; The Coniagas Reduction Co., Thorold, Ont., Side Suction Centrifugal Pump; The Penman Mfg. Co., Brantford, Ont., Triplex Power Pump; Messrs. Chappell Bros., St. Omer, Que., Duplex Packed Piston Pump; The Hollinger Gold Mines, Ltd., Timmins P.O., Porcupine, Ont., Duplex Pump.

Messrs. Wailes, Dove & Company's "Bitumastic" Solution and Enamels have been adopted for painting the whole of the Gates and Structural Steel work in connection with the Panama Canal, at a cost of $335,000.00, probably the largest individual contract ever given for painting. Machan & Hebron, St. Francois Xavier St., Montreal, are the Canadian representatives.

Montreal, P. Q.—Tenders have been invited by the Cedar Rapids Manufacturing and Power Co., Montreal, for the first section of their power scheme. This will comprise the construction of the dyke and part of the power house, at an estimated cost of about $2,000,000.

St. Jerome, P.Q.—Tenders have been awarded for the hydro-electric system at St. Jerome, P.Q., as follows:—Transmission and distribution, Marchand & Donnelly, Ottawa, $10,875; generators, Swedish General Electric Company, Montreal, $5,475; switchboards, Hill Electric Switch & Manufacturing Company, $3,496; water wheels, William Hamilton Company, Peterborough, $4,743; penstock and concrete work, Laurentian Construction Company, Montreal, $33,814. The generator equipment consists of two 150 k.w., 4,000 volt, 327 r.p.m. waterwheel type units with direct-connected exciters supplied through the manufacturers' Canadian agents, Messrs. Kilmer, Pullen & Burnham, Toronto.

Calgary, Alta.—The city of Calgary has awarded a contract for a 2,500 k.w., 60-cycle, 3-phase, 2,300 volt turbo-generator. The complete equipment is being supplied by Messrs. Laurie & Lamb, of Montreal, and will consist of a Belliss & Morcom steam turbine, a Vickers, Limited, alternator, as well as an air pump, the necessary piping, etc.

Calgary, Alta.—The corporation of the city of Calgary have placed an order with Messrs. Kilmer, Pullen & Burnham, Ltd., for one 1,000 k.w., 400 r.p.m., synchronous, self-starting, railway motor-generator set, manufactured by the General Electric Company of Sweden, to be installed in their new substation on Ninth Avenue west, city of Calgary.

The Davidson Electric Company have established themselves at 174 Notre Dame Street east, Winnipeg, where a general contracting and supply business will be carried on. This company will also specialize in the repair and maintenance of fine electrical instruments. The new firm is composed of Jas. A. Davidson and Chas. E. Long, both practical electricians of many years' experience.

ending December 31, 1911, shows that the net profits were $1,010,153, being an increase of 45 per cent. over the best previous year. The total assets of the company now amount to $6,586,751. Extensions to the plant have been an important factor during the past year. The extensions to the warehouse, factory and pattern building were completed early in 1911, and the plant has been further increased by the new main machine shop aisle now nearing completion, after which the necessary machine tool equipment will be installed. The former boiler plant has been rebuilt with all labor-saving appurtenances, and in such a way as to permit of the installation of extra units as required. The construction of all these buildings has been carried out on lines of solidarity and permanency.

GENERAL MANUFACTURING.

Duck Lake, Sask.—A by-law will shortly be submitted to raise $3,000 as a bonus to the Dominion Milling Company which is about to start up here.

Port Arthur, Ont.—W. Scott, of the Pigeon River Lumber Company contemplates the establishing a pulp mill at this place and has asked the city council for supply of power up to 2,000 horse power.

Ottawa, Ont.—Fire in the building occupied by Hugh Carson, Ltd., trunk and valise makers did damage to the extent of $7,000. The loss is covered by insurance.

Bowmanville, Ont.—It is very probable that a new manufacturing industry will be located here. If present plans are carried into effect it will employ 400 to 500 hands, male and female. Details are not given.

Port Colborne, Ont.—The Robinson Bros. cork factory was partially destroyed by fire recently. About 6,000 square feet of corkboard, the machinery and belting were completely destroyed.

London, Ont.—T. Dexter & Son are considering the purchase of property and enlarging present flour mill or else constructing an entire new mill at a cost of $40,000.

The Battle Creek Breakfast Food Co., Dundas street, have had plans prepared by architects Moore & Munroe for erection of a factory; 4-storey and basement, 50 x 100, modern in every detail. Cost $25,000.

A company is being formed to equip a chain of ten cent stores all through the district and a charter will be applied for at once. Complete store fittings and equipment will be needed. Address F. H. Brewster, London.

Plans are being prepared for biscuit factory to cost $250,000, for D. S. Perrin & Co. Architects, Moore & Munroe, London, 6-storey, stone foundation, brick construction, steam heating, electric light, gravel roofing. Biscuit, box and candy making machinery required. Elevators and boilers required.

Ald. Hubert Ashplant has plans prepared by architects Moore & Munroe for erection of sample rooms on Carling st., 5-storey, 33½ x 75, stone foundation, steam heating, electric lighting, gravel roof, telephones, elevators and modern fittings for 30 sample rooms will be required. Tenders received by Moore & Munroe. Cost $25,000.

Not an Enterprise for the "Quitter"

¶ "If there is one enterprise on earth," says John Wanamaker, "that a 'quitter' should leave severely alone, it is advertising. To make a success of advertising one must be prepared to stick like a barnacle on a boat's bottom.

¶ "He must know before he begins it that he must spend money—lots of it.

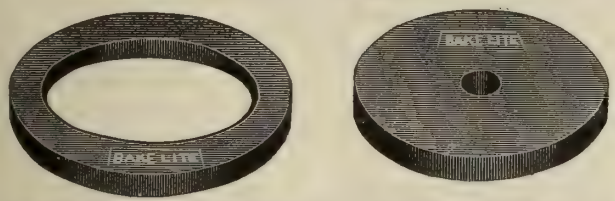
¶ "Somebody must tell him that he cannot hope to reap results commensurate with his expenditure early in the game.

¶ "Advertising does not jerk; it pulls. It begins very gently at first, but the pull is steady. It increases day by day and year by year, until it exerts an irresistible power."

These are the telling points about

Bakelite

Valve Discs



They will not leak under high temperature, excessive pressure or when used in acids or other special liquids. Neither cold water, dry or superheated steam has the least effect upon them. BAKELITE Discs are a gas-tight fit.

BAKELITE is a successful substitute for expensive metal. Its structure is fibrous, giving strength and hardness. It can be reground and refaced, always retaining a uniform surface. It cannot be injured, except by accident or friction.

Remember Bakelite PUMP VALVES do not warm with changes of temperature.

Order your valves fitted with Bakelite Valve Discs and stop that perpetual annoyance and expense caused by leaking valves. Depend upon it, Bakelite Valve Discs will not leak.

WRITE FOR PRICES OR ASK YOUR DEALER.

For over 35 years the makers of the best leather belts.

and this does make a difference to you.

Engineer Fred says—

"Here's the pulley for you, gentlemen. It's the Oneida—the biggest thing in the shop. Watch the belt hug her—and see how well the oval crown fits.

"You can run her up to any speed and she doesn't mind it.

"The weather can't shrink her. There's no waste power here.

"She weighs only half as much as cast iron. She's made good in every sense of the word—and here's her record in chopping down expense."

Oneida Steel Pulley

Range of sizes—6″ to 126″ diam., 2″ to 40″ face, 1″ to 8½″ bore.

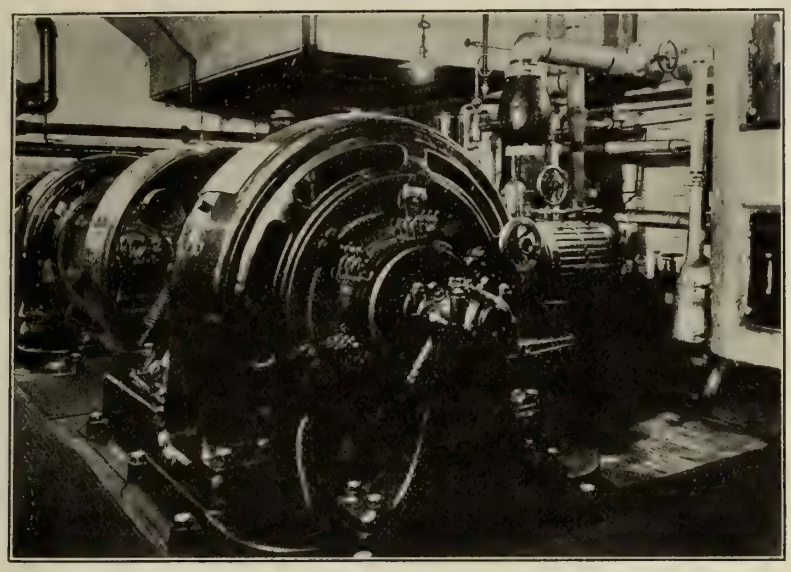
An Engine Installation that "Made Good"



"Every one is a McEwen."

Here is a corner of the Engine Room of the Lowndes Company, Limited, Toronto, showing two 12x12 and one 16x16 McEwen Engines, direct connected to electric generators.

The 16 x 16 engine was purchased after six years' use of the two 12 x 12 engines.

This is one typical example of the "make good" qualities of the McEwen. We can point to dozens of similar "repeat order" installations throughout the country.

We build the engines in simple and compound units up to 700 Horse Power, a size for every service.

The McEwen Engine bulletin and list of users sent on request.

The Waterous Engine Works Co., Limited

EFFICIENCY

Is the main consideration in your Power Plant. There is only one way to obtain it, and that is:—

BUY THE BEST

equipment you possibly can and DEVELOP YOUR OWN POWER. By so doing you save money and in addition you have a steady service all the time. The power is not off just when you need it the worst. Such service means EFFICIENCY.

Illustration shows H. D. Goldie Corliss & Vertical High Speed recently installed by us.

The Best Quality of Material and Workmanship

are used in the construction of Goldie & McCulloch Engines, Boilers, etc. There is nothing better made.

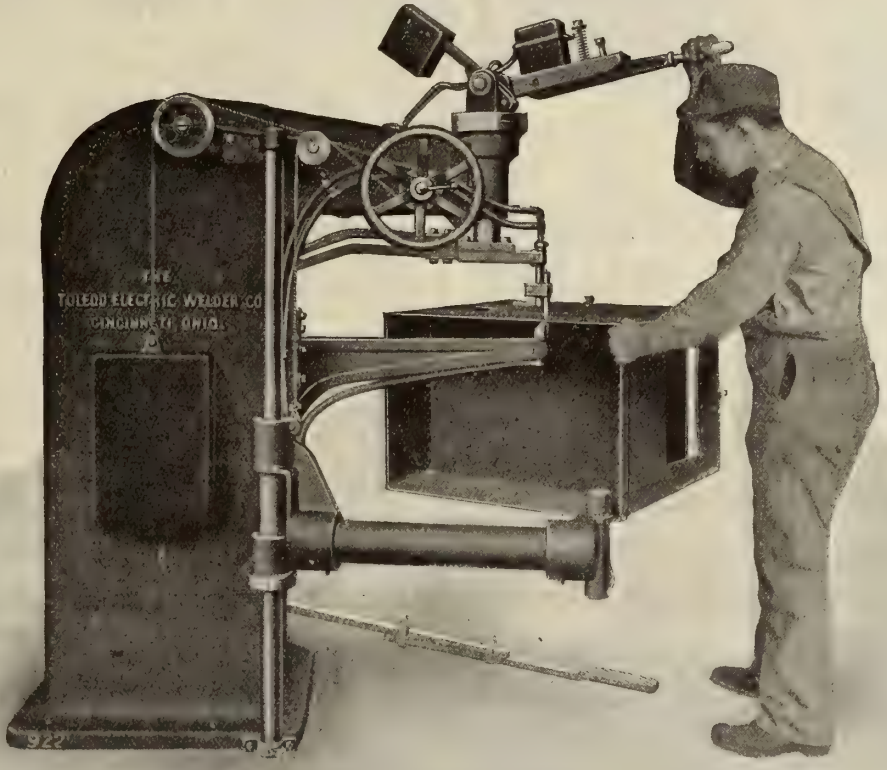
SPOT WELDING

NO HOLES TO PUNCH. NO RIVETS USED.

Quicker than Riveting and Better.

HERE'S OUR LATEST.



No. 150 SPOT WELDER.—Welds 1/8 inch to 1/8 inch. Welds 30 ga. to 30 ga.

Next month we'll show another view of this same machine, showing how it operates when foot treadle is attached.

It has a ball bearing adjustable table.
Raises or lowers by means of the hand wheel.
Table drops to within six inches of the floor.
Can be raised level with the die points.
Good for any kind of bulky stock.
Saves the expense of a helper in handling stock.
The head swivels—operator stands in front or at the side.
The current is turned on and off automatically.
The foot treadles can be attached in 30 seconds.

BUT—OUR NEW 32-PAGE BULLETIN No. 12 TELLS ALL ABOUT THEM. IT ALSO TELLS ABOUT BIG AND LITTLE SPOT WELDERS. JUST SAY YOU WANT IT—IT'S YOURS FOR THE ASKING.

Manufacturers are saving from 50 to 85 per cent. by the use of the **TOLEDO** Welder. Tell us the kind of work YOU want to save money on. If you can't make money with a welder—we'll tell you.

NO LEASE. NO LICENSE. NO ROYALTY.

DON'T BORE!

Use Shelby Seamless Steel Tubing

For use as Bushings, Hose Mandrels, Roller Bearings, Lathe Spindles and many similar parts, the only preparation necessary on a Shelby Seamless Tube is to cut it to the proper length. You can easily see the saving of time and expense over boring a steel bar.

New uses are being found every day by ingenious mechanics for Shelby Seamless Tubing. From being a dozen years ago merely a specialty for the use of Bicycle Manufacturers, Shelby Seamless Tubing has come to be a stand-by in hundreds of shops. It has thousands of applications, many of them simple and direct, like those mentioned above, but in countless other instances it is merely the basis of more complex structures.

To meet the demand for special forming operations, our mills have been fully equipped for carrying out the heaviest and most difficult kinds of special work on tubing of all sizes and thicknesses, such as flanging and bending tubes for automobile axles, upsetting drill rods, swedging, expanding, coupling and tapering tubes.

If you will tell us the nature of your work, we will be glad to suggest ways in which you can save on manufacturing costs by using either simple or modified Shelby Seamless Tubing. Write

YOU DON'T NEED A SLEDGE TO TAKE THIS CUTTER OFF A MILLING MACHINE SPINDLE.

Prying with a bar and hammering with a sledge have often broken cutters and seriously injured the machine. All these troubles are eliminated with the

New B. & S. Inserted Tooth Face Milling Cutter

This cutter is made with the taper hole to fit a split sleeve of steel that is screwed on to the spindle nose. It is keyed to the sleeve and is drawn on to the taper of the sleeve by a drawbolt. As the drawbolt is tightened, the sleeve contracts and securely grips the spindle. But no matter how heavy the cut, a few turns of the drawbolt instantly release the cutter.

There are many other features of this cutter worth considering.

Our Cutter Catalogue gives full information. Send for a copy, it is free.

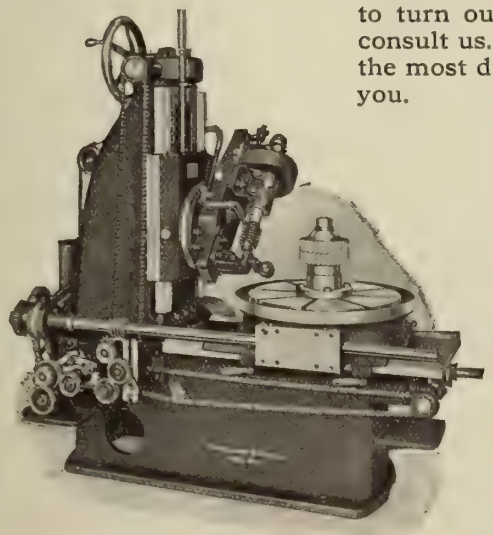
You Can Cut Spiral Gears As Easily As Spur Gears

On the S & S Gear Hobbing Machine



If you have trouble with your present gear cutting department or are unable to turn out accurate and noiseless running gears, you should immediately consult us. A substitution of spiral gears for spur gears has solved some of the most difficult problems. What we have done for others we can do for you.

S & S Gear Hobbing Machines are equipped with an ingenious device for cutting spiral gears which is strongly protected by patents and cannot be imitated by anyone, nor can the same results be produced by any other method.

S & S Machines are, by virtue of their patented features, the only practical gear hobbers for cutting spiral gears of any lead to absolute accuracy within the limits of .00001 independent of the feed gears and without necessity of tedious figuring.

Right and left hand spirals cut with same hob. One hob will cut any size gear of one pitch.

Write for particulars.

Men in Charge

—Owners —Superintendents
—Managers —Foremen
—Purchasing Agents

¶ These are the men you want to reach with your advertising.

¶ There is a reason why CANADIAN MACHINERY AND MANUFACTURING NEWS is THE medium you should use in a large way to reach these men.

¶ Given a good journal—well edited, illustrated and well printed, the paid-up circulation would be small were not a vigorous campaign carried on, both by mail and personal work.

¶ CANADIAN MACHINERY is well edited, well illustrated and well printed—the one source in Canada of timely, reliable, first-hand information to mechanical men.

¶ But we are not satisfied with simply publishing a good journal. Our thoroughly-trained, salaried subscription men are out hustling for subscriptions in every province of Canada—and getting the business, or we want to know the reason why. In addition, we are represented in practically every railroad shop and other large shops by special agents, who are well paid for every order sent in—and every mail brings orders from these men.

¶ No machine shop, foundry or metal working shop of any class, whether large or small, is overlooked by our subscription plan.

¶ Above is one GOOD reason why you should not overlook this journal as your strongest aid to more business in 1912. There are many others.

Want to talk it over? Write us.

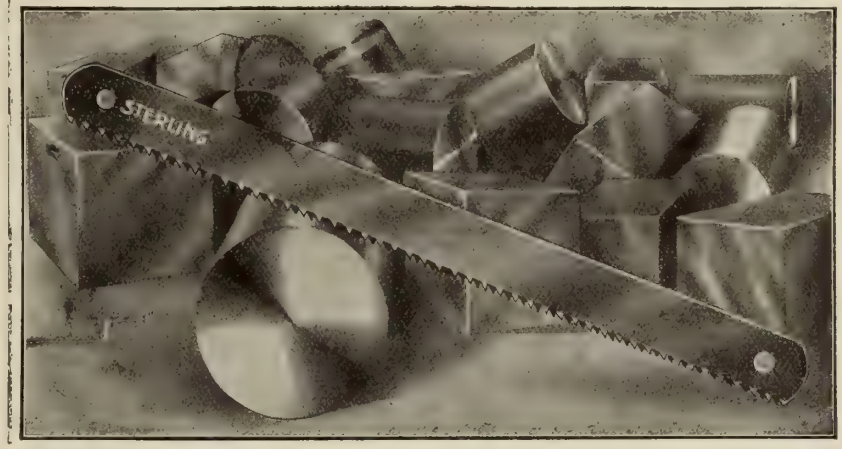
THE LUFKIN RULE CO. OF CANADA, LTD.
WINDSOR, ONT.

"Sterling"
Hack Saw
Blades

Have no equal.

A trial will

convince you.

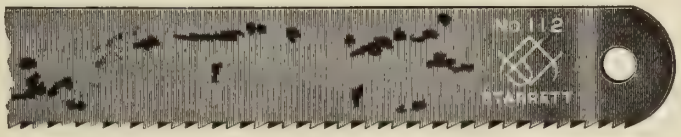


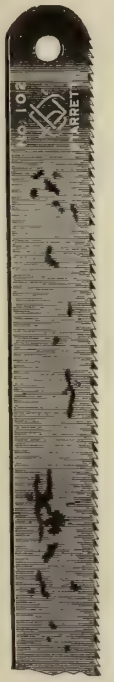
Manufactured by

DIAMOND
SAW AND
STAMPING
WORKS,

Buffalo, N. Y.

Write for Catalog
and Prices.





Suppose—

a hack saw lasts an hour and costs 6 cents, and the time of the man using it costs 30 cents—doesn't it pay to use a new sharp blade?

But every time a blade is changed, just so much of the man's time is lost—doesn't it pay to get the blade that lasts longer and the blade that cuts faster while it *does* last?

THE STARRETT HACK SAW

cuts faster because there is a particular kind made for every job, and each of the keen square teeth does its share of the cutting.

It lasts longer because the best steel goes into its composition, and our superior tempering process makes it uniform throughout. It won't shell off. **Try Just One Starrett.**

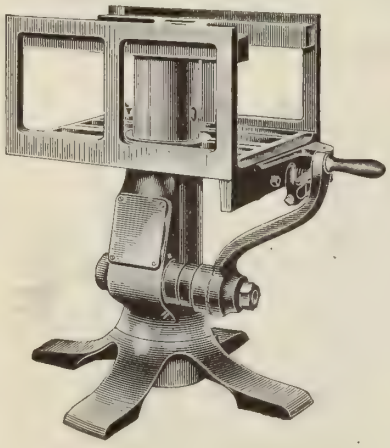
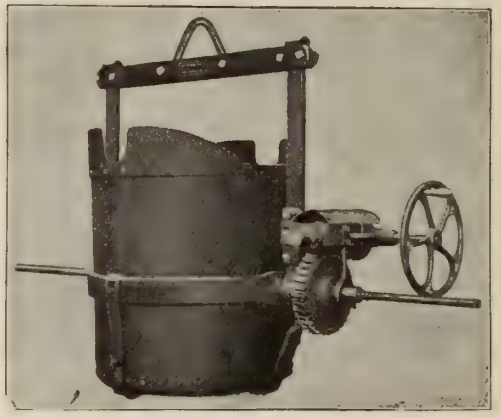
PROMPT SHIPMENTS





This is something that every foundryman wants when he orders his goods.

We are prepared to give you service, quality, and lowest prices on anything from a DUST BAG to a CUPOLA. If you are not using EUREKA BLACKING you ought to. It's the BEST on the MARKET.

EUREKA CORE COMPOUND (a pitch core compound) of 100% purity, mixes much the same as flour and as readily taken from the castings. Will not blow and is cheaper than flour.

No. 48 PLUMBAGO, a high graphitic carbon lead, will do the best kind of work, if you are looking for that kind. Write for latest catalog of Polishers' and Platers' Supplies.

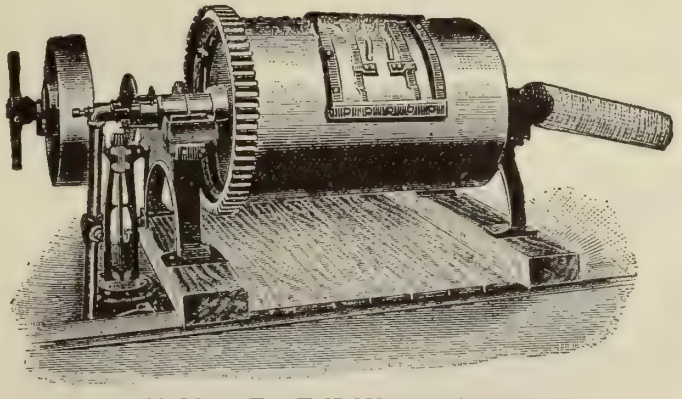
A GOLD MINE

SAVE YOUR IRON



SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

A WINNING HAND

THE Foundryman who uses **Stevens' Genuine East India Plumbago,** or **Ceylon Lead,** always plays a winning hand. He is betting on a sure thing.

I import this article direct from India, because it is absolutely the best plumbago produced in the workshop of Dame Nature.

Its use enables the foundry to do the work sometimes left for the machine shop to finish.

I manufacture everything used in a Foundry and in a Polishing and Electroplating Department.

In buying from me you are buying from first hands.

It costs as much to sell one thing as to sell them all. I sell them all for a small slice of profit. I take the small slice and give you the rest.

Take Time to Write Me a Letter.

THE TIGHTENING GRIP!

Foundrymen everywhere are being squeezed by a pressure that wrings from them their rightful gains.

They must pay a ***continual tribute*** to "Make-overs"—the profit devouring beast of their Foundry.

There is but one charm by which this beast can be destroyed—it is

SHELTON METALLIC FILLER

—the Foundryman's "Medusa".

DON'T PAY TRIBUTE

which means, ***don't make a casting twice!***

Make-overs are unnecessary.

Here is a chance to stop your losses.

Shelton Metallic Filler is guaranteed to fill in and completely obliterate blow holes, sand holes, etc.

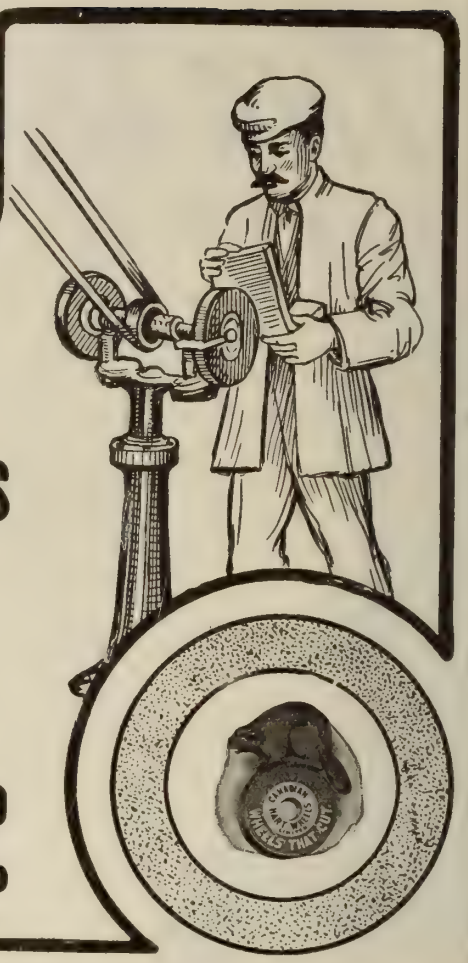
It becomes part of the casting itself, is durable, and can never be detected. It has been used with great success for many years.

Better write to us at once.

Shelton Metallic Filler Co.

DERBY, CONN.

The Daily Grind



The daily grind of mechanics engaged in using abrasive wheels is made much more effective if their machines are fitted with

CANADIAN HART CORUNDUM WHEELS

WE would like you to understand the new McDougall Lathe. It is a machine of reserve strength and capacity. It can handle your "high speed" steel tools at their maximum speed. You get the benefit.

Note the headstock construction first. See the very wide bearing surfaces and massiveness. The whole machine from headstock to base is like a solid rock. We have done everything that will make this headstock right. It must wear. It must resist strain.

The big bearings are fitted with deep oil chambers and ring oilers. Your lathe is automatically protected against accidental wear and excessive loosening up of the bearings by the operator's omission to oil. Only when you get wear taken care of, have you a headstock which is able to resist strain. Its wide bearings are not only kept automatically in shop perfection, but they take the greatest strain a cutting-tool can give through the work and a spindle in high-carbon steel. The automatic oil device protects the quality of your lathe output by protecting the bearings, so chattering is impossible

Look at the work of a McDougall Lathe some day. You will see a smooth, clean tool-cut, shining and bright. This shows the even feeding of the work from a firm headstock against a firmly-held tool.

The carriage and apron are non-springing. The action of the tool depends on the solidity of bearing given it by the carriage. This carriage is supported by full "V" bearings, and flat bearings as well. There can be no "lost motion" in the carriage, and none at the cutting edge of the tool.

The tool feed reads to thousandths both ways on the compound rest The automatic feed is of the safety type, so interlocked that your mechanic cannot operate both feeds (screw and rod) at the same time.

Here you have a clean cut from a solidly-held tool working against a solidly-held casting, in a lathe so protected by automatic oiling that it always maintains its accuracy and strength. You can adjust this tool to 1-1000 inch. You cannot break tool or work by accidental operation of both feeds at one time. No breakdowns.

Now look at the tailstock. It has a quick-acting sleeve lock device. This permits quick change of work. In addition the tailstock is secured to the webbed and non-springing bed of the lathe by four bolts with top adjustment. Both kinds of tailstock changes are easy and quick—they save workmen's time.

Take another look at this McDougall Lathe. See how well the gap is supported, and how deep the gap is. Though this is a gap lathe, it is as solid as a standard type, because the base is carried under the entire gap opening. Here you have a gap lathe without a single disadvantage of the gap opening and the deteriorated work it often causes.

Get a McDougall Lathe like this in your factory equipment. Its adjustability, speeds, capacity and practicability make it one of the most perfect machine tools. It is particularly economical where a variety of kinds of lathe work have to be done on a single lathe, because it is a quick-change machine.

Suppose you write us your problem. And to-day, now. The McDougall lathe will raise quality and lower cost.

To Gas Engine Manufacturers:—

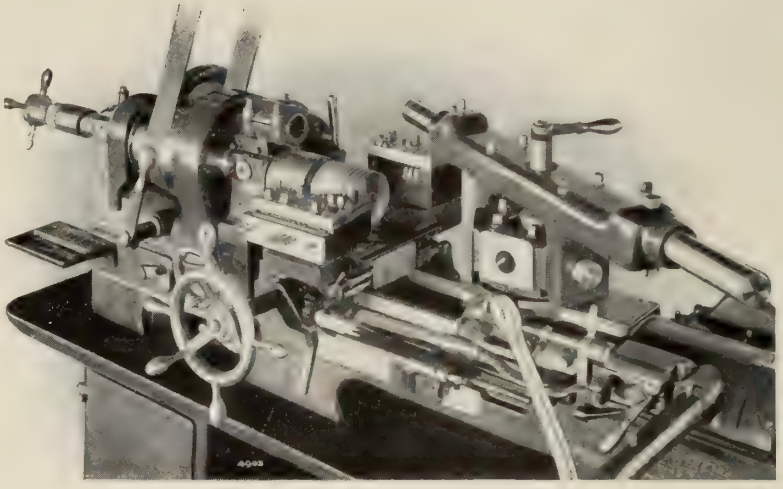
Gas Engine Pistons and Piston Rings rapidly and economically machined on

P. & W. Standard Turret Lathes

with Special Tool Equipment

Simultaneously turns, faces and grooves pistons.

Produces a piston with uniform thickness of walls.

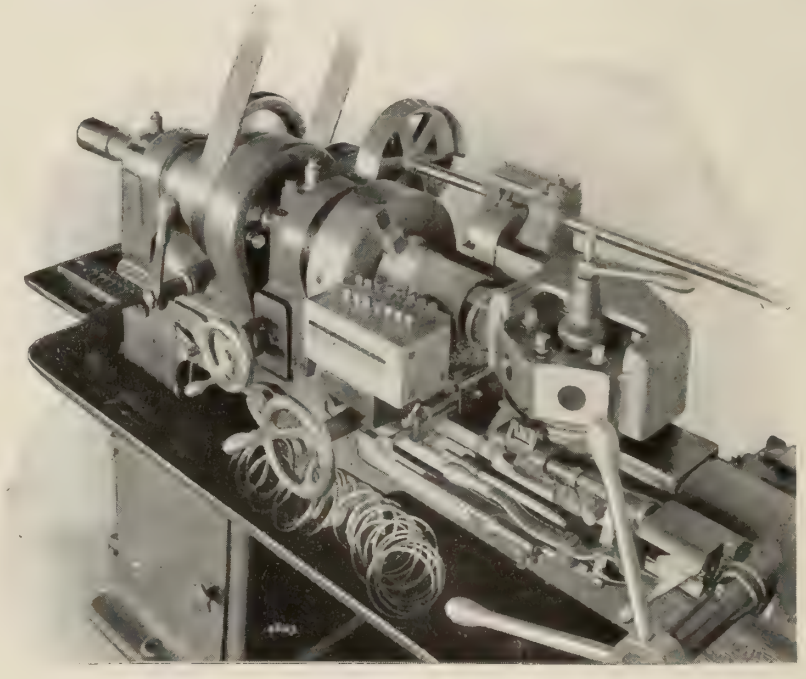


Turns out a piston of greater accuracy and at a greater saving than any other machine on the market.

P. & W. Turret Lathe with Tool Equipment for finishing Gas Engine Pistons.

Piston rings bored inside, eccentrically turned outside and cut off simultaneously.

Automatic features enable one man to operate several machines



These are not special machines, but standard P. & W. Turret Lathes.

The special tool equipment, can be readily removed in a few minutes, leaving the machine ready for any standard turret lathe work.

P. & W. Turret Lathe with Tool Equipment for finishing Eccentric Piston Rings.

The ease with which these equipments may be removed and interchanged, makes possible the furnishing of both piston and ring equipments, for the same machine if so desired.

Inquiries concerning your individual requirements are solicited. Write for catalogs and illustrated circulars.

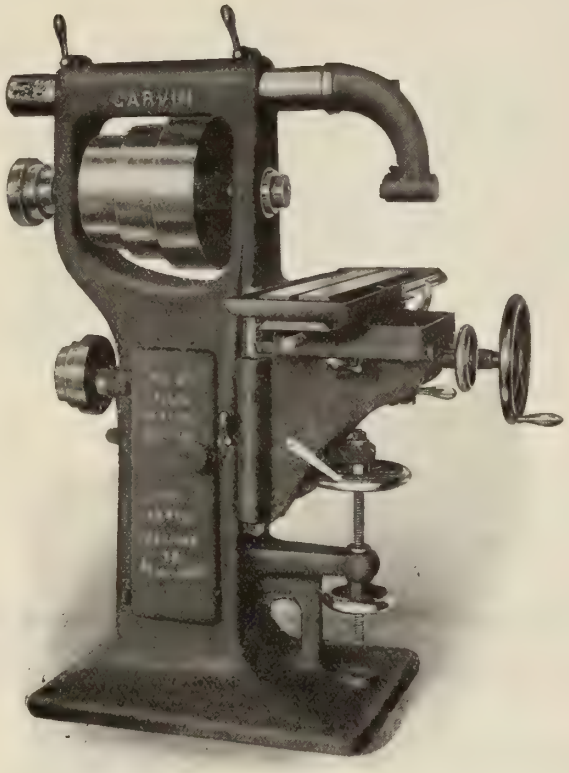
A GARVIN MILLING MACHINE FOR EVERY NEED



No. 21 Plain Milling Machine.
Use Code.....ABSORB.

Fully 80% of the Milling Machines manufactured are used on manufacturing work, and a great majority of this 80% is used on what is called long set-ups. Did it ever occur to you that a simple Milling Machine without frills is made just as accurately as the so-called standard machine, and would effect a great saving in the first cost of your machine tool equipment.

Again, a less expensive operator can be used.

Think this over and investigate the merits of our No. 21 Plain Milling Machine. Made especially for manufacturing work and used by large concerns in gangs of six, to one operator.

Machines are simple and accurate, having lots of power, and enough feed and speed changes to take care of the work they are intended for.

Adjustments—18 x 6 x 13 inches.

Fig. 4
Fig. 5
Fig. 6
THE HEALD MACHINE COMPANY
HEALD
easily have two or three contact faces giving in that way six or nine contact points around the circumference of the gear
NUMBER OF TEETH
One point that merits your careful attention is in regard to the design and operation of chucks in holding gears when the number of teeth is not a multiple of three
When the teeth are in multiples of three, the jaws will of course naturally come just 120 degrees apart, but when the number comes otherwise, as for instance 31 or 32, instead of 30 or 33, a certain adjustment of two of the jaws is necessary to care for this, whether rolls between the teeth, or jaws making contact at the bottom of the tooth spaces are used
This adjustment must be in a true circumferential line to maintain the correct distance of the roll or jaw from the center of the chuck and will amount in either case to one-third the circular pitch of tooth to tooth at the pitch line, for which suitable provision has been made, as shown by the slots in the jaws in Fig 3 and on page 11
FAULTY DESIGNS
It has come to our attention that chucks are being made for holding such work in which the adjustment of the roll or contact point is made in a straight line across the face of the jaw, instead of in a circumferential line parallel to the pitch circle
This introduces a serious error, inasmuch as the roll is moved along a tangent line which increases its distance from the center of the gear, and therefore, is not in proper relation to the pitch circle to correctly locate the gear
In other words, the two jaws which have been moved to correspond to the number of teeth in the gear, are then at incorrect distances from the center of the chuck and will not, therefore, properly locate the gear for the grinding
Even if provision is made for radial adjustment of these jaws it is impossible to tell exactly how much adjustment to make especially when the gear has been hardened and there are no true surfaces to work from
All these difficulties disappear and accurate work is assured when using a collet fitted with jaws designed according to the systems we recommend

IT'S TITLE

"Practical Hints ON Internal Grinding"

It is full of the solutions of just such problems as those indicated on the left hand page. Its reading matter is both interesting and valuable —examine the right hand page and you will see how and why. We're getting requests for it every day from Managers, Superintendents, Foremen and Machinists. And the unanimous opinion is—"Just what I've been looking for." If you have not as yet sent in a coupon, here is one for you.

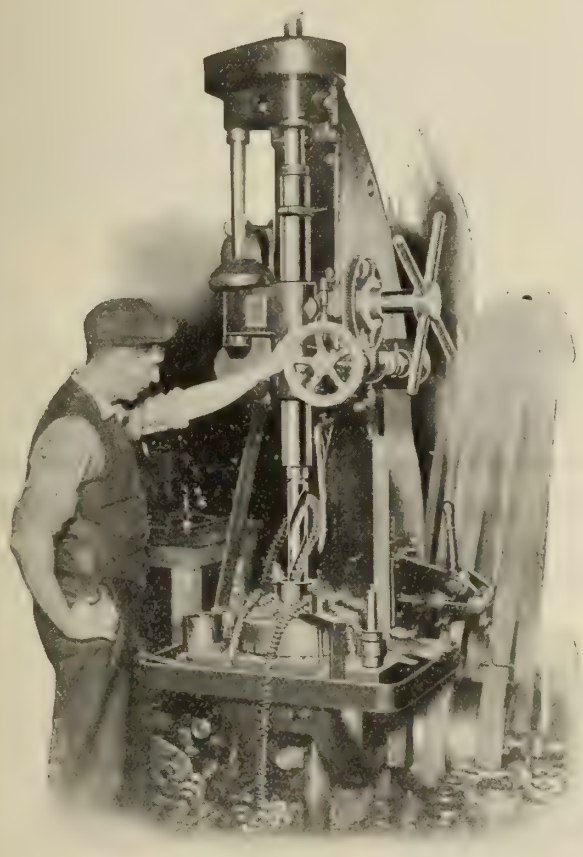
"DETROIT" TWIST DRILLS

Trade Mark

Trade Mark

WATCH THEM WORK



Our trade-mark is the High-Efficiency Sign. It guarantees you absolute satisfaction or a refund of your money. Your Dealer is authorized to make this refund. If he does not carry "Detroit" products write us. Write us anyway: we want you to have our Catalog "R" and Helpful Hints for the Machinist.

The only way to really see and truly appreciate "Detroit" Drill quality is to put one in your Drill Press and watch it work. Give it a good tough job—a job that has spoiled many another make of drill—and test it out under your everyday working conditions; under your own supervision.

By actual service "Detroit" Drills are proving that they drill more holes through greater thicknesses of metal in less time without re-grinding than other makes of drills.

One of the largest Auto Plants in the world writes us as follows:—

"We have given the sample 1⅝ in. Taper Shank High Speed Drill a very thorough test and find same *superior to any other drill which has been used by us for this particular work.*

"We are issuing our Purchase Order for one dozen of these drills to come forward at once. We may also state that the recent shipment of regular High Speed Chucking Reamers is giving the best of results."

(Name on request.)

Don't allow the "let well enough alone" policy to rule in your shops. Get a "Detroit" Drill from your dealer, or write us direct. Test it out. Prove for yourself, that "Detroit" Drills give maximum results at minimum expense; that they reduce Shop Costs.

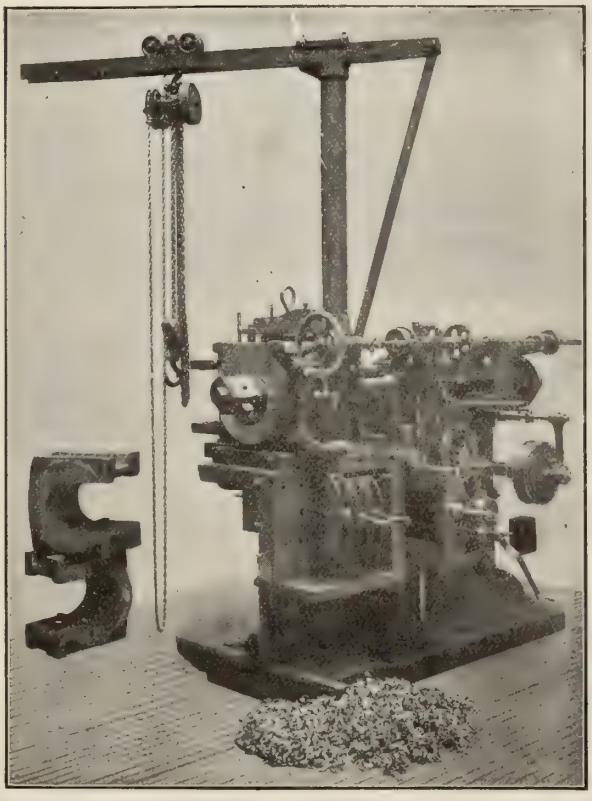
The Morton Draw-Cut Railroad Shaper



This shaper will crown and plane axle boxes, plane the brass shell to fit, and plane shoes and wedges at a saving of from 25 to 40 per cent. over ordinary methods. This machine is also equipped for doing a general line of shaper work.

For further particulars address

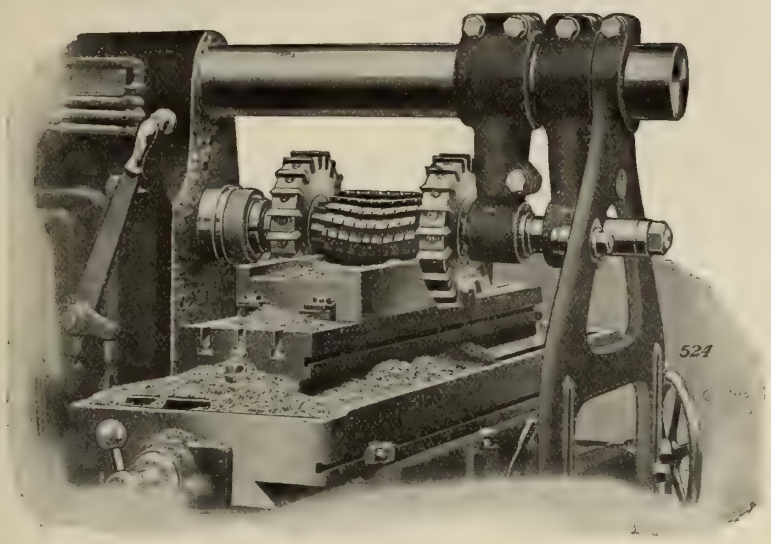
The Morton Manufacturing Company

MUSKEGON HEIGHTS, MICH.

Also builders of Cylinder Planers and a full line of Draw-Cut Pillar Shapers.

The advertiser would like to know where you saw his advertisement—tell him.

NINETEEN CUBIC INCHES PER MINUTE



THE total width of surface roughed off at one cut on these gray iron castings is 16½ inches—maximum depth of cut 3-16 in.—length of cut on each piece 8¼ in.—largest cutters 10½ in. diameter, running 21 rev.—6.3 feed.

The pieces are held in a string jig, removed as fast as traversed by the gang and others chucked in their places.

The pieces are made in lots of 125 at a time and an entire lot is regularly milled on a No. 4 Plain High Power Cincinnati Motor Driven Miller at this enormous rate without stopping to sharpen the cutters.

It takes a powerful, rugged machine to do such milling, and it must go through without vibration—otherwise the cutters would be dulled, forcing a reduction in the feed, long before an entire lot of pieces is finished. Our machines are designed for this kind of service.

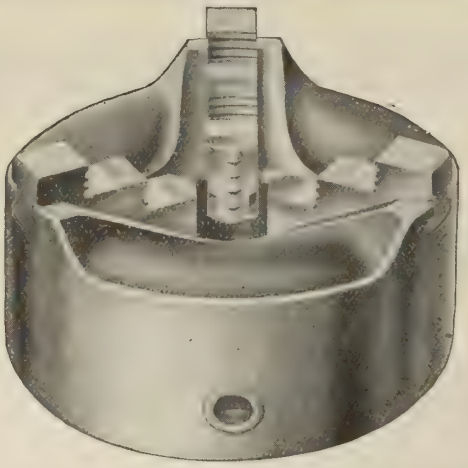
COLUMBIA HIGH SPEED CHUCKS

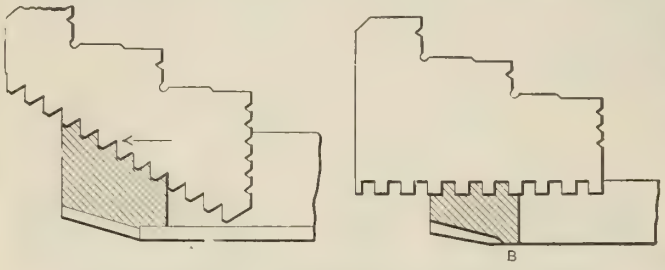
are especially adapted for work with High Speed Steel.



COLUMBIA UNIVERSAL CHUCKS

are the Chucks for High Power Machine Tools.

We claim that the Columbia Chuck is the best Universal Chuck that has ever been offered to the world. Also that in view of its power to "stand up" under the most strenuous service and its altogether unique lasting qualities it is the lowest priced tool of its kind in existence. The work gripped in a Columbia will not slip and permits the use of high speed steel to its full cutting capacity.



Comparison of Pitch of Columbia with ordinary chuck.

Note the pitch of the scroll thread, it is much finer than the ordinary universal chuck, thereby increasing its gripping power and wearing surface.

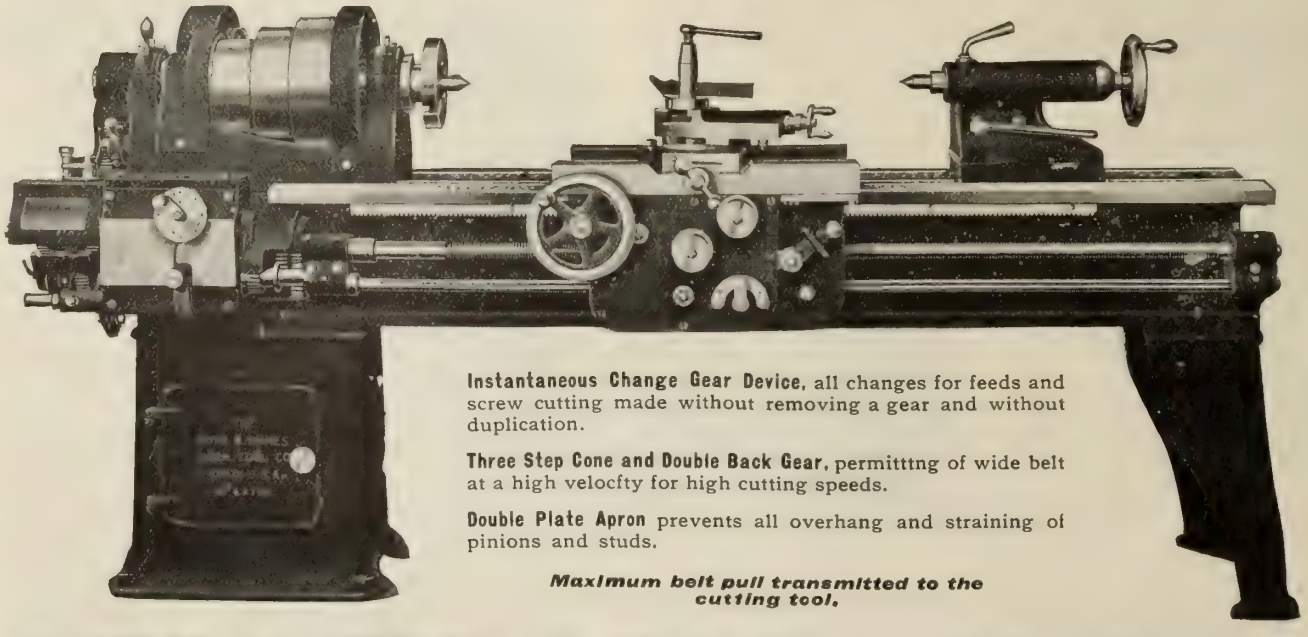
Ask us for illustrated circular with full description.

Schuchardt & Schutte

307 Coristine Bldg. Montreal, Que.

18" Instantaneous Change Gear Engine Lathe

Double Back Gear **Double Plate Apron**



Instantaneous Change Gear Device, all changes for feeds and screw cutting made without removing a gear and without duplication.

Three Step Cone and Double Back Gear, permitttng of wide belt at a high velocfty for high cutting speeds.

Double Plate Apron prevents all overhang and straining of pinions and studs.

Maximum belt pull transmitted to the cutting tool.

SCHUMACHER & BOYE Engine Lathes CINCINNATI, OHIO, U.S.A.

The Boye & Emmes Machine Tool Co. Successors

Save On The Single Piece As Well As The Big Job

The Bullard Vertical Turret Lathe is not alone a manufacturing machine—the very features which make it a good manufacturing machine also reduce the cost of the individual piece.

The Vertical Turret Lathe is ready to save on face plate work of every description within its capacity. Vertical Construction, Ample Power and Rigidity, Multi-Cutting, Quick Speed Change, Centralized Control, Automatic Lubrication—these cost-reducing factors save on the single piece as well as on the big job. It does not keep the foreman on the jump looking for the right job. Nor does it require an expensive special tool equipment for each job.

Investigate. Find out how much less YOUR face plate work will cost done on a Vertical Turret Lathe.

We'll be glad to put some interesting facts and figures before you.

Send for Treatise on Face Plate Work, No. C-15, NOW.

COCHRANE-BLY COLD SAWS

Illustration shows No. 4-B (6-in. capacity).

A durable and efficient tool designed to handle a large variety of stock for general shop use.

Provided with four (4) changes Automatic Feed.

Automatic Return of Carriage, Oil Pump and Tank.

Regular equipment handles, rounds, squares, I-Beams, angles, etc,, and by means of special equipment, small round or square stock may be cut in multiple, giving increased production with low cost of operation.

We make

Cold Sawing Machines (5 sizes.)
Automatic Saw Sharpeners (2 sizes.)
Die Filing Machines (2 sizes,)

Ask for catalogue and estimates of cutting time on special work.

COCHRANE-BLY COMPANY

ROCHESTER, N.Y.

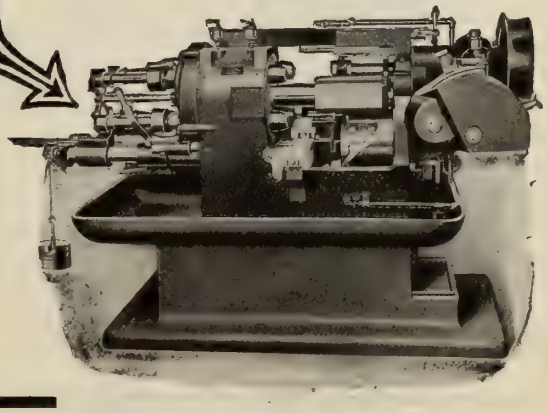
The Turret Lathe that Ensures a Fast, Accurate, Economical Output

The Gridley Automatic

A greater output can be secured per day, because the rigidity of the tools and general design of the machine permit heavier cuts and coarser feed to be maintained.

Greater Accuracy can be secured and maintained on Gridley Automatics because a stiffer and more efficient type of cutting tool can be used. The tool is held rigid, without overhang and cannot spring or wobble.
Save much labor cost because one man can operate 3 to 6 machines at once.

"GRIDLEY" Multiple Spindle



WRITE FOR ILLUSTRATED CATALOGUE

We manufacture both "Single" and "Multiple" Spindle Automatics.

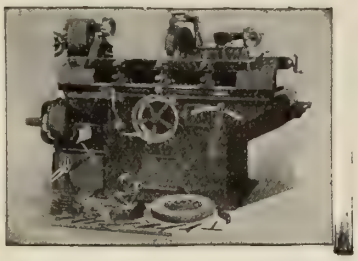
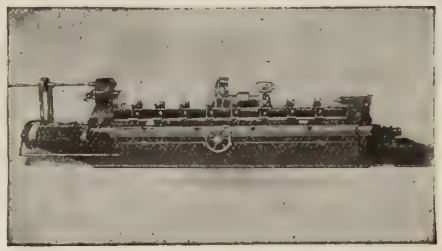
THE LANDIS LINE—



Landis Plain Grinding Machines

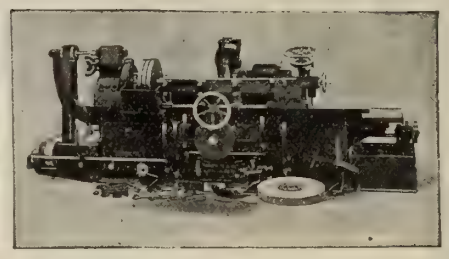
10 in.x 20 in., 10 in.x30 in., 12 in.x32 in., 12 in.x42 in., 12 in.x66 in., 12 in.x96 in., 12 in.x120 in. These machines are intended for finishing straight and taper spindles, shaft rolls, tubing and all other work within their range which can be revolved on dead centres.



Plain Self Contained Grinding Machines

Standard Sizes: 16 in.x72 in., 20 in.x96 in., 20 in.x 120 in., 20 in.x144 in., 20 in. x 108 in.

These manufacturing machines are adapted for straight and taper cylindrical shafts, spindles, pistons, corliss valves, plungers, tubing and are especially desirable for grinding hardened steel and iron rolls.



Plain Grinding Machines with Gap

These are our 16″ and 20″ swing Plain Self-contained Machines built with gap in the bed to suit the location of the projection on the work.

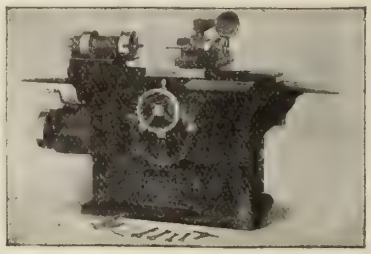
Descriptive and Illustrated Literature for Each Size.

Landis Universal Machines (Large Type)

No. 1 (10″ x 20″), No. 1½ (10″ x 30″), No. 2 (12″ x 32″), No. 3 (12″ x 42″), No. 4 (12″ x 66″).

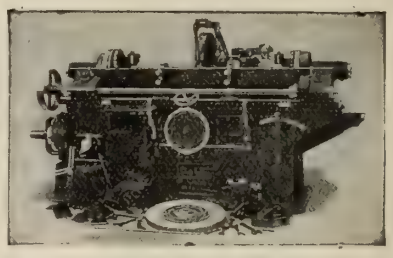
Nos. 2, 3, 4 (also built with 16″ swing) are used for finishing tools and a variety of straight or taper parts (both external and internal) as are common to the tool-room, machine shop, railroad shop, etc.

Attachments such as magnetic chuck, gear cutter attachments, cam grinding attachment, side mill grinding attachment, etc., can be used on these machines.



Landis Internal Grinding Machines

This machine is intended for straight and taper internal grinding. The fixtures for these machines will grind holes ¼″ diameter or larger and up to 12″ long.



Landis Crank Grinding Machines

These machines are designed for grinding single or multiple throw crank shafts used in gas and small steam engines.

GARDNER Vertical Spindle DISC GRINDER

This is the largest Disc Grinder, of any type or make, on the market. The disc wheel is 53 inches in diameter and is driven by bevel gears within the base of the machine. These gears run in oil bath and are completely shielded from any dust or dirt. A dust chamber lies under outside edge of disc wheel and connection is made in rear for attaching exhaust system.

A special pneumatic press is furnished for cementing new discs to wheel.

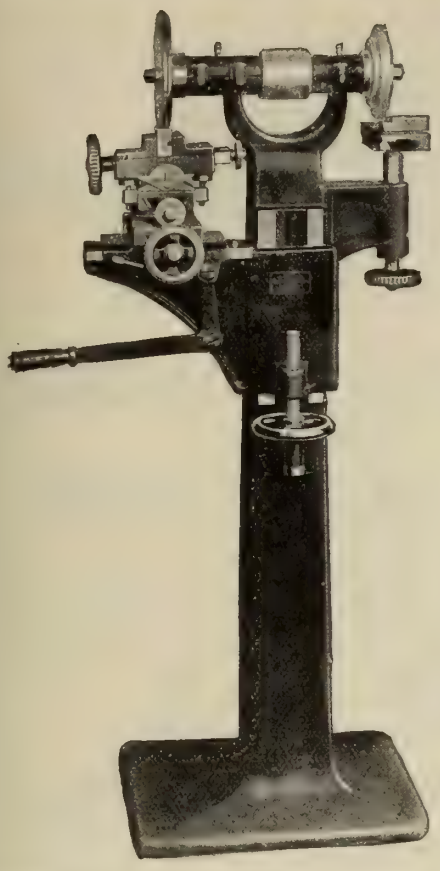
We also make our No. 24 machine with direct motor drive.

Simply place the pieces to be finished on the revolving Abrasive Disc and leave till finished. A number of pieces, according to size, can be ground at once. Operated by unskilled labor.

Scores of our No. 24 machines are in daily use. We will tell you where you can see one in operation.

Ask for free folder "Vertical Spindle Disc Grinding."

GARDNER MACHINE COMPANY — The Disc Grinding Authorities — BELOIT, WISCONSIN



What Is Your Method of Grinding Thread Chasers ?

You know that it is practically impossible to keep threading tools in shape or to regrind them satisfactorily by hand.

The Geometric Chaser or Die Grinder

touches up all Chasers of a set uniformly and keeps them in condition for accurate work.

The machine is adapted for grinding any make of thread Chaser, whether of a stock or special type, and is also equipped with a second grinding wheel for ordinary tool grinding.

In shops where much screw cutting is done, one of these machines will save its first cost in a short time in labor alone, and Chasers that are kept properly ground will last a great deal longer and do far better work than Chasers that are subjected to the hit-or-miss hand grinding.

Let us send you our Special Booklet describing this Chaser Grinder.

BLOUNT'S

Wet Tool Grinder

Will put the finest edge on Tools at the smallest cost.

The operating cost of this high grade Grinder is very low, and the efficiency is so high that the up-to-date plant cannot afford to be without it.

Absolutely no wear of parts, as the propeller of the centrifugal pump, furnishing a constant supply of water, is loosely fitted and does not touch the pump case at the nearest point.

The main bearings are long and self-oiling, and the machine can be run continuously if desired, to avoid loss of time in starting and stopping. A sleeve cap which extends to a point above the water line prevents leakage without the use of packing.

Write for catalog on our Grinding and Polishing Machinery.

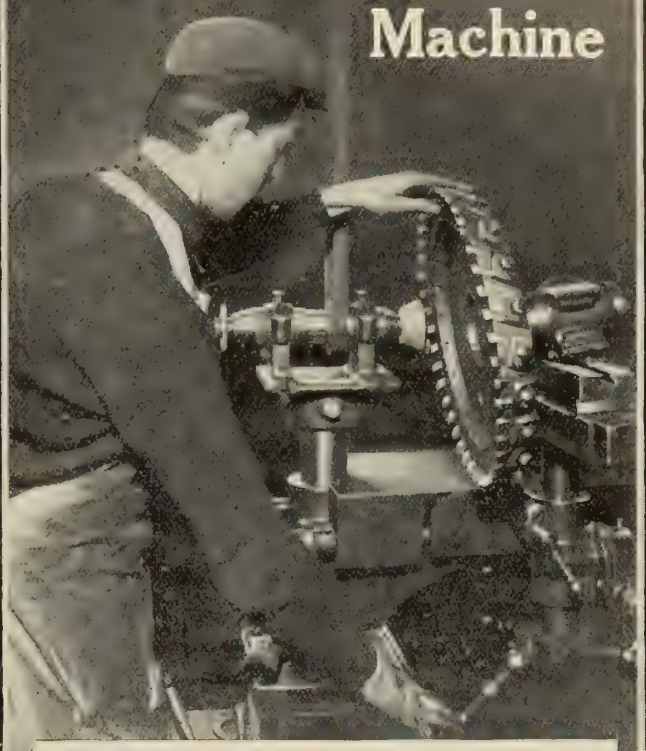
EVERETT, MASS., U. S. A.

An Aloxite Wheel Does Some Big Work On a Little Machine



ORDINARILY, the machine in question was used only on small work—it wasn't powerful enough to drive a slow-cutting wheel on a big job.

The operator put on a little Aloxite Wheel—it cut so fast and free that he is now running the machine far beyond its original capacity.

As an example, he backed off a 16-inch inserted tooth milling cutter—the wheel took off .003 of an inch from each tooth—never burned—held its shape and size—and made a mighty efficient machine out of a limited tool grinder.

Again it's the case of having the right wheel—an Aloxite wheel—in the right place. We have many more records of the merits of Aloxite wheels—write for our "efficiency booklet."

A Wise Decision

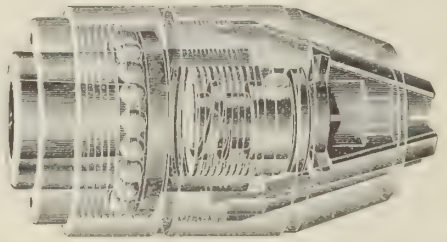
When the Purchasing Department orders Morrow Ball bearing, self tightening, quick releasing, hand operated drill chucks exclusively, it shows that someone in authority has made a "Wise Decision"—a decision not reached without careful comparison and thorough test, under practical conditions. Morrow drill chucks have made their reputation through actual service. They are the most accurate, longest wearing and most economical drill chuck made. They are used in the best plants, they are used by the best workmen, because they can be depended on for accurate and quick work. They are offered by the best dealers, because they never fail to meet requirements. Made in five sizes. Send for Catalogue.

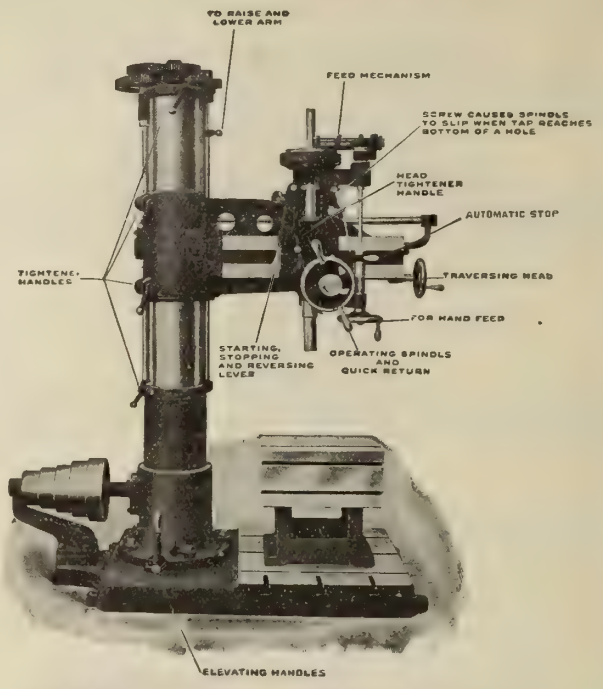
Manufactured by

The Morrow Manufacturing Co,

ELMIRA, N.Y.

Canadian Agents—The A. R. Williams Machinery Co., Toronto, Winnipeg, Vancouver; Williams & Wilson, Montreal.





SIMPLE TYPE RADIAL DRILL

a line of machines we manufacture in conjunction with our Standard Type Radial Drills. This machine is very simple to operate, has great pulling capacity, and is of the very best material and workmanship. Tests we have made show that they do highly accurate work.

Now probably you have some work for a Radial Drill, but still do not wish to invest any great amount of money; and if that is the case, write to us for further particulars of our SIMPLE TYPE RADIAL DRILL.

The proposition we will submit to you is a little out of the ordinary, and since a postal card will bring it to you, we would consider it good business acumen to investigate.

We specialize in power transmission problems and will see you through your difficulties. Special facilities for rush orders.

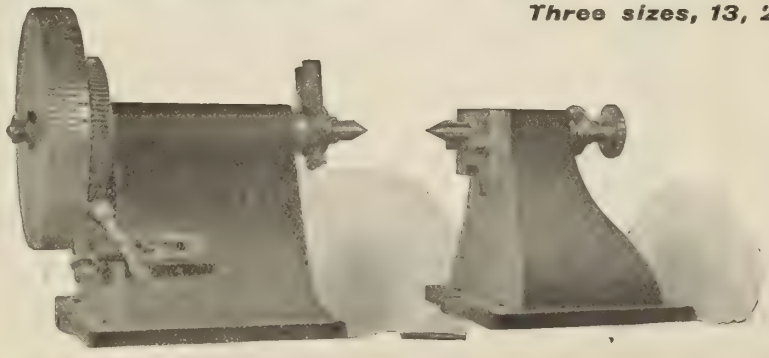
J. C. WILSON & CO., Glenora, Ont.

When in a hurry, wire us.

IMPROVED PLANER CENTRES

With Index of wide range.

Three sizes, 13, 20 and 36 inch.



YOU WILL LIKE THEM for their precision and convenience. Adapted for fluting rolls, planing gears or any work which has to be carried on centres to be planed or milled, or which requires to be accurately spaced. A valuable improvement is, that the index plates which are of large diameter, are cut through, like a gear tooth, which permits the use of a much stronger pin than is possible with a drilled plate. Work and index plate turn together, with a worm and gear, which are readily disengaged when not required. Special index plates for your particular requirements.

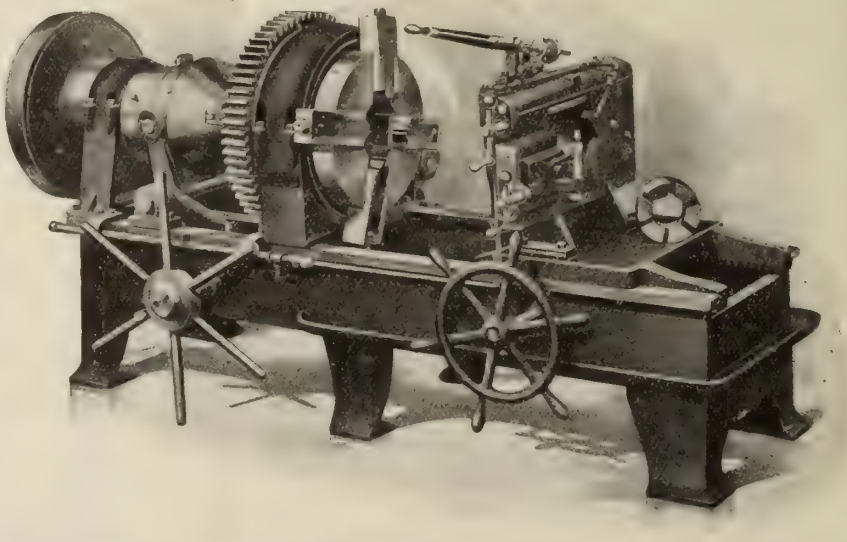
They Are All Doing It Now. *What?*

Using BIGNALL & KEELER Pipe Threading Machines. *Why?*

Because we have advanced ideas in pipe machine construction and operation. Quick adjustment, large capacity and strength make them both satisfactory and profitable. The fit and finish of threads cut on B. & K. Machines insure tight joints.



Become a User.

No Hunting for Parts

Hunting for parts is frequently the habit of those who use ordinary die stocks — it means the loss of much time and money. With the

"Beaver" Adjustable Die Stock

four sizes can be obtained with one set of dies, through a twist of the wrist.

You will save much time through the use of a "BEAVER." When your dies wear out you will have to buy one new set of dies instead of four.

The Beaver is absolutely accurate and has proven itself the most convenient.

Get our quotations on power machines, any size from 1/8-in. to 12-in., motor, belt, gasoline or steam driven.

An investigation will prove valuable to you. Write for circulars and prices.

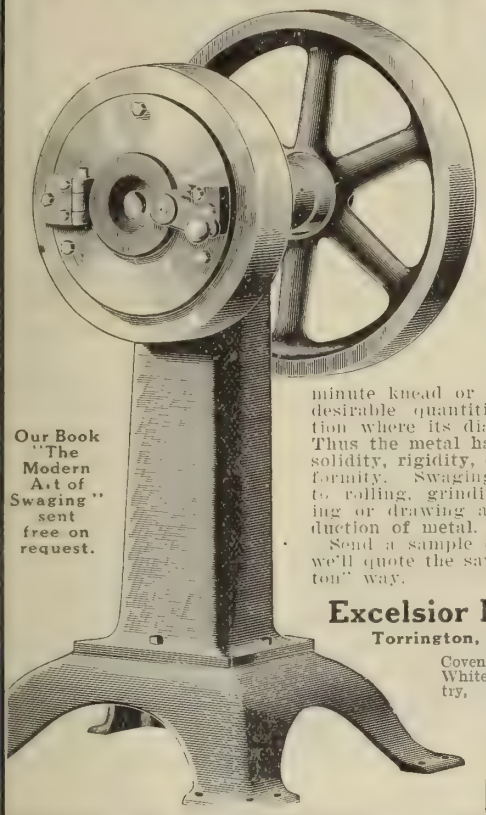
REDUCE METAL
WITHOUT WEAKENING IT



Our Book "The Modern Art of Swaging" sent free on request.

Swage The Dayton Way

The Dayton Swaging Machine does not sacrifice one particle of strength of the metal being reduced. From 2,000 to 6,000 taps per minute knead or squeeze all of the desirable quantities into the portion where its diameter is reduced. Thus the metal has added strength, solidity, rigidity, elasticity and uniformity. Swaging is far superior to rolling, grinding, milling, turning or drawing as a means of reduction of metal.

Send a sample of your work and we'll quote the saving by the "Dayton" way.

High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

J. A. SHERWOOD, Agent

Hoffman Steel Balls

(Manufactured in England)

are made of the very finest high carbon chrome steel, and are all guaranteed to be perfect spheres, correct to standard size within one ten-thousandth of an inch. The surfaces are glass-hard, with a very high elastic limit, while the interiors are softer, though considerably toughened.

Hoffman Standard Journal Bearings

consist of two hardened rings of finest steel, with curved ball races and a single row of balls in a floating cage of drawn gunmetal—the best anti-friction metal for this purpose. Also made full of balls when required, though we do not recommend this.

Hoffman Standard Thrust Bearings

are made both single and double, on the same lines as the journal bearings, and in exhaustive tests, under a great variety of conditions, they have proved thoroughly efficient and reliable.

Hoffmann Ball Bearings have successfully carried loads up to 500,000 lbs., at speeds of from 1 to 30,000 revolutions per minute. For further information write

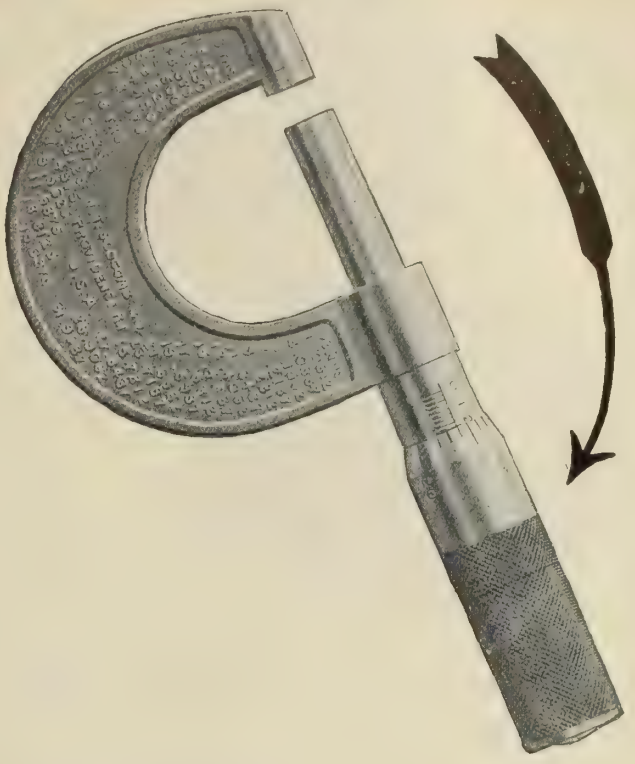
THE NEW FRICTION THIMBLE



You probably know what a Friction or Ratchet Stop on the end of a Micrometer is. This is the same idea, but arranged so that the thimble slips when more than a certain amount of pressure is applied. With the Friction or Ratchet Stop Micrometer it is necessary to use two hands—one to hold the tool, the other to work the stop.

With this New Micrometer you work the Friction Thimble with the same hand hand that holds the tool. Quick, accurate measurements and always the same, Frame is polished and has raised figures, showing decimal equivalents,

Don't be late in ordering one of these tools. The best adjustments that are in any micrometer

"Make it in Maisonneuve."

Maisonneuve—the Ideal Manufacturing place for the Metal Worker.

Why not build your factory in Maisonneuve, in old Quebec? Few places offer the manufacturer the opportunities presented by this enterprising town. Maisonneuve is just about three miles down the St. Lawrence River from the heart of Montreal, and possesses all the attributes that go to make up an ideal manufacturing centre.

In population Maisonneuve has grown from eight thousand to thirty thousand in about five years' time, and is to-day the home of some of the largest industrial concerns in the Dominion of Canada. The workmen in Maisonneuve in the majority of cases own their own homes, and the town is singularly free from labor troubles.

Among some of Maisonneuve's industries are:
Montreal Locomotive Works., Kingsbury Footwear Co., Warden King Co., United Shoe Machinery Co., Vickers-Maxim Co., Ltd.. St. Lawrence Sugar Refinery, The Montreal Steel Works, The Ramsay Biscuit Co.

Here are a few reasons why Maisonneuve is the place where you should build:—

First—Shipping facilities by rail. Three railroads, C.P. R., G.T.R. and C.N.R. ("Spurs" may be run to factory sites.)

Second—Shipping facilities by water. The St. Lawrence River, great concrete sea docks for ocean liners and up-the-lake boats. (The Vickers-Maxim dry-dock is being constructed here.)

Third—Power. Low rates and the benefit of competition between two companies, the Montreal Light, Heat and Power Co.. and the Dominion Light, Heat and Power Co.

Fourth—Ten years' exemption from taxes.

Fifth—Water. Low water rates, and on many of our factory sites water may be obtained from the river.

Sixth—Improvements. Sewers, water, gas, and so forth, are in practically all factory sites.

Seventh—Labor. Here is where Maisonneuve excels every other manufacturing town in the Dominion. Without doubt the finest labor market in Canada, both for skilled and unskilled labor. The workingman here owns his own home, and labor troubles are unknown.

Why Didn't We Protect Those Windows, too, With Fenestra Sash ?

What *water-tightness* is to an ocean liner—
What *burglar-proofness* is to a bank—
What *strength* is to a sky-scraper—
Fireproofness is to a modern industrial building.

It would seem hardly less logical to handicap the watertight compartments of a ship with frail partitions, to offset the 3-foot cement floors of a vault with a wooden trap-door, or to construct a Singer building on a doubtful footing, than it is to build a modern factory of fire-proof construction, equip it with sprinkler-systems, fire-doors and fire-alarms, and then to demoralize the whole chain of expensive and otherwise carefully planned fire-protection by tolerating the weak link of wooden sash.

Scientific factory construction relegates wooden sash to the day of clapboard walls, plank floors and shingle roofs.

Where else can you reasonably class them ?

FENESTRA FIRE PROOF SASH

glazed with ordinary wired glass is positively the last word in fire-resistance as applied to windows.

Common sense dictates that.

Actual fires have proven it beyond question. In a fire at Stoneham, Mass., in September, a building equipped with FENESTRA SASH was practically surrounded by a burning varnish factory. Reglazed after the fire, the Sash were as good as new. Photographs on request.

Remember, too, that FENESTRA SASH also *light* and *ventilate* a building better than any others. They're made to suit individual needs.

If you are interested in the planning or construction of a building where *light*, *fresh air*, and *fire protection* are essentials, let us send you our "Fenestra" Catalog.

STEEL AND RADIATION, LIMITED

SHAFTING BEARINGS

Countless thousands of dollars have been wasted in power, oil, metal, labor, etc., in a mistaken idea of economy by using cheap or inferior metals on shafting bearings. The following letters show the value of Magnolia Metal for that service:—

THE CITIZENS' ELECTRIC CO., LIMITED

Smith's Falls, Ontario, January 28th, 1911.

Gentlemen.—Yours of the 27th inst. to hand and noted. Regarding the boxes you mentioned lined with "Magnolia Metal" would say we have a 60 ft. 3½ in. shaft running 300 rev. per min., running all night and every night in the year, put up over **10 years ago**, and still running perfectly, and has never been touched in that time except for oil, and one tablespoonful will run each box for 12 hours.

Yours very truly, J. A. SCROGGIE,
Eng. and Electrician.

KAUKAUNA GAS, ELECTRIC LIGHT AND POWER CO.

Kaukauna, Wis., June 15th, 1911.

Gentlemen'—I have used Magnolia Metal for the past six years. I placed some of this metal in chain oiling boxes on a 4 7/16 in. line shaft, running 278 R.P.M., in October, 1905. This shaft has been running continuously 24 hours a day ever since. I have not found it necessary to rebabbitt any of these boxes to date, nor have I had any burn-outs. I am also using Magnolia Metal for belt driven dynamos, ranging in speed from 900 to 1275 R.P.M., and have found the metal much more satisfactory than any other I have used. Yours truly, N. B. MONTGOMERY,
Chief Engineer.

SPECIAL OFFER

GOODYEAR

Power-Saving Rubber Belting

Goodyear Rubber Belting stands for power saved and money saved. It is built up of plies of rubberized fabric cured and vulcanized into one solid piece. It neither slips nor stretches. It has the cohesiveness of rubber with the enormous tensile strength of close woven, long fibre cotton fabric from which ***all stretch has been taken out.***

Goodyear Rubber Belting is manufactured by a process that makes it proof against steam, water, weather and rot. Made in all three grades and all sizes. For Pulp, Paper, Saw Mills—*all* mills where horse power transmitted is large and demand for tensile strength great. Used by biggest lumber mills and manufacturing plants in the Dominion. *Outlives, outlasts* all other belts,

Rot-Proof Mill Fire Hose

Goodyear Underwriters is a hose built to meet the specifications of the Associated Factory Mutual Fire Insurance Companies. Tube used of highest grade NEW rubber. *Won't* harden or crack with age. Special circular woven fabric with least expansion or elongation under pressure. Antiseptically-treated to make it rot and mildew proof.

The strongest, most reliable hose for all mills and factories. Insist on *Goodyear Underwriters, the hose with the black and yellow stripes.*

Non-Chipping Conveyor Belts

Built for all purposes. For conveying crushed stone, grain, coal, ore, etc.

Made in all thicknesses of face to suit requirements of buyer. Rubber face made of toughest stock possible, to prevent cutting and chipping. Gives longest and most enduring service.

We also manufacture other rubber goods such as tires, all kinds of hose and belting, rubber packing, etc.

Write us to-night for catalog and prices.

Our sales of the last four months fifty per cent. greater than those of last year. Defective goods returned only $23.93

This is the Chain you need—

Morse

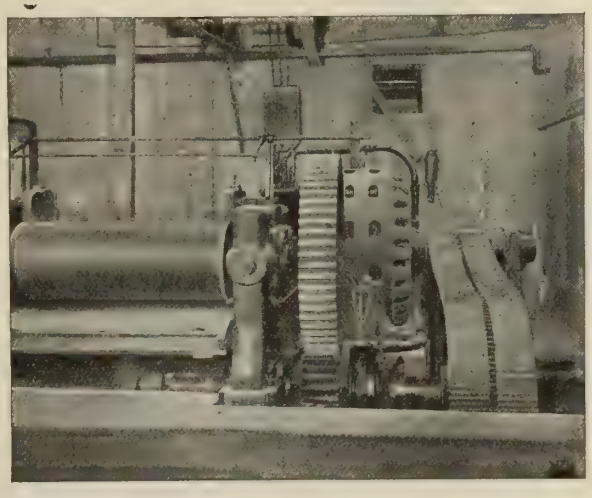
"Rocker-Joint" Silent Chain

It means less power lost in transmission, because practically 99% efficiency is maintained.

Greater production—more power transmitted means more work done.

Less maintenance cost—it lasts longest and requires least repairs.

Note the different construction of the joint. Two pins are used in each joint instead of one and a bushing. The two-pin joint requires no bushing. This construction, known everywhere as the "Rocker-Joint," is an exclusive feature of the Morse Silent Chain.



200 Horsepower Morse Silent Chain Drive

435 to 85 R.P.M. on 84-inch centres. Sprockets 23 and 117 teeth Two chains, 1½-in. pitch, 10-in. wide. Chain speed, 1250 feet per minute.

The rolling action of the pins, one against the other as the chain moves, practically eliminates friction from the chain joint. That is why it is so successful.

Morse Silent Chains are made in all sizes and pitches, for drives ranging from ¼ to 3000 horsepower.

Special machinery for making large sizes insures prompt delivery.

PUMPS

The superior excellence and splendid results shown by

"FAIRBANKS-MORSE"

pumping machinery are largely due to the fact that for many years we have manufactured Hydraulic Machinery of all descriptions. We are therefore able to build pumps which are properly designed and adapted to every-day use. This is of the greatest importance in a first-class pump, for the usefulness of an engine may be lost if the pumping machine is badly designed.

You will get all these important features when you purchase a "FAIRBANKS-MORSE" pump.

Let us solve your pump problems.

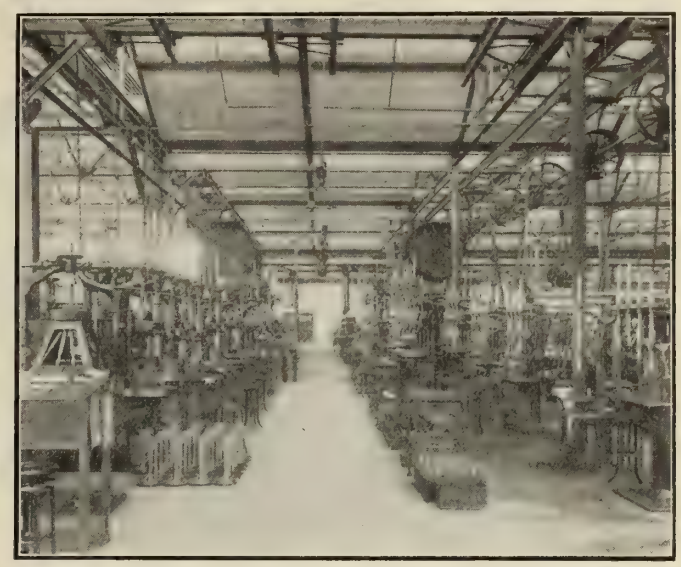
The Cincinnati Milling Machine Company's New Plant

By C. T. R.

The impression that a visitor gets when taking a trip through this plant is, that here are shops on which an immense amount of thought was expended to secure, as nearly as possible, ideal conditions in regard to light, heat, ventilation, sanitation, and all that goes to make the life of the workmen more pleasant; in other words, a plant constructed and equipped for the highest efficiency.

THE new shops of the Cincinnati Milling Machine Co., Cincinnati, Ohio, were planned some years ago when the company's business had grown beyond the capacity of the old equipment.

The Cincinnati Milling Machine Co.—Gear Cutting Department.



The Cincinnati Milling Machine Co.—Drill Press Department.

During the search for a new location, Mr. Fred. A. Geier, President, conceived the idea of a factory colony, grouped about a central power plant. He secured options on a 100-acre tract, ideally located as to topography, railroads, street cars and labor. Three other companies who were in need of better facilities, at once joined in the original project, and formed a real estate development company, which assumed the work of laying out streets, railway connections, sewers, etc. The central power plant is managed by a separate company, whose stock is owned by the various plants served, now numbering seven. It furnishes power, light, heat, compressed air, water, sprinkler service, etc.

The Cincinnati Milling Machine Co.—Bird's-eye view of the plant. 275,000 sq. ft. floor space (exclusive of power plant).

The Cincinnati Milling Machine Co. retained seventeen acres for foundry and machine shop purposes. The first buildings were erected in 1907, and formed the present plant of the Modern Foundry Co., which is owned by the stockholders of The Cincinnati Milling Machine Company. It has a daily melting capacity of thirty tons of iron for machine tool castings, all of which, including the largest milling machine column castings, are made on molding machines. Its practice includes a number of processes which have been developed to produce castings of high quality, for each of the important parts of their milling machines.

The first section of the machine shop was erected in 1909 and 1910, and was

operated in connection with the old plant, until the final three-storey section was ready for occupancy in the Fall of 1911. The machine shop proper is a single-storey brick and steel building, 16 feet high under the trusses and 26 feet under the peak. A 60-foot section

The Cincinnati Milling Machine Co.—Ch ucking Lathe and Automatic Department.

along the eastern length of the building is 21 feet under the trusses, and is traversed by five-ton traveling cranes. The roof is concrete and steel, covered by Carey roofing. It is supported by hollow cast iron columns of such small diameter that there is an absence of that sense of obstruction which is sometimes present in shops using built-up steel columns. They are hollow, and also serve as downspouts. The roof trusses are provided with gusset plates to facilitate placing countershafts and craneways in either direction. The cuts show some of them in use carrying the beams from which motors are suspended. The floor is concrete, re-inforced, 8 inches thick, making individual foundations for machines, except in the cases of the largest planers, unnecessary. It also provides that stability for the testing and assembling departments, which is so essential for satisfactorily doing this work. That part of the shop which is occupied by the planers, has a floor 12 inches thick, to carry the weight of the smaller planers and the masses of heavy material in process of manufacture grouped around them.

In preparing the ground previous to laying the concrete floors, the sod was all removed and the surface rolled with a 10-ton roller; then levelled and rolled a second time. A covering of tar felt was placed over the entire surface to hold out moisture, and the concrete was placed directly on this covering. The re-inforcing consists of ¼-inch twisted bars laid at right angles to each other, placed 12 inches apart and wired together at all intersections; thus making the entire floor a monolith. This style of floor proved so satisfactory during more than a year's experience in the first part of the building that it was unhesitatingly adopted for the final addition recently completed.

The south front of the building is three stories of re-inforced concrete, monolithic construction, faced with brick. The upper floors are 60 feet deep by 380 feet wide. The first floor is a continuation of the one-storey shop, forming an unbroken L-shaped room, 380 feet by 585 feet. The purpose in adding two upper storeys over this part of the building was to provide suitable quarters for the various offices, and space for those departments which earlier experience proved, should preferably be separated from the main machine shop.

Offices.

On the third floor are located the offices, the engineering and clerical departments. The upper floor was selected for offices, because of the desirability of having them on the floor highest above the ground level on account of being quieter, cleaner and airier. They occupy the central part of this floor.

The floors of all the offices, as well as the floor of the main entrance to the building, are laid with ceramic tiling and there is a 6-inch sanitary base of green tile; the whole producing not only a durable and sanitary effect, but also a very pleasing ornamental effect. Access to the offices is by means of an elevator. The western end contains an auditorium having seating capacity for 600 people. There is also provision for a kitchen and dining rooms. Immediately adjoining the engineering section on the east is the tool-making department, which brings it in close touch with the tool-designing department.

The second floor is devoted to stock-rooms for finished details, and for as-

The Cincinnati Milling Machine Co.—Engine Lathe Department.

sembling cutter grinders, dividing heads and other attachments. This is the only manufacturing done outside of the main machine shop floor; the tool and jig-making department on the third floor being in no sense a part of manufacturing. This portion of the second floor was set aside for this purpose solely to provide a place where the dividing heads could be assembled as a specialty, this being precision work; and experience has shown that it can be accomplished more satisfactorily in an isolated department.

Cooper-Hewitt mercury vapor lamps, which furnish sufficient illumination for all purposes without the use of incandescent lights except in a few very special cases. The offices and engineering departments are lighted by the indirect system, using Tungsten lamps in clusters. This soft, diffused and evenly distributed light, with its entire absence of glare and shadows, is proving as satisfactory as good daylight conditions.

Heating.

The buildings are heated by the Evans-Almirall system of forced circulation hot water. In the saw-tooth, single-storey part of the bulding, the circulation pipes are placed on the lower cords of the trusses immediately below the window space. This arrangement warms the cold air descending from the roof windows, and prevents all discomforts from drafts caused by descending currents of cold air from these windows.

Ventilation.

The provisions for ventilating have also had a sufficient test during the extremely hot weather of last summer, when they proved entirely adequate; the shop having been held at a comfortable temperature and with an ample amount of fresh air at all times.

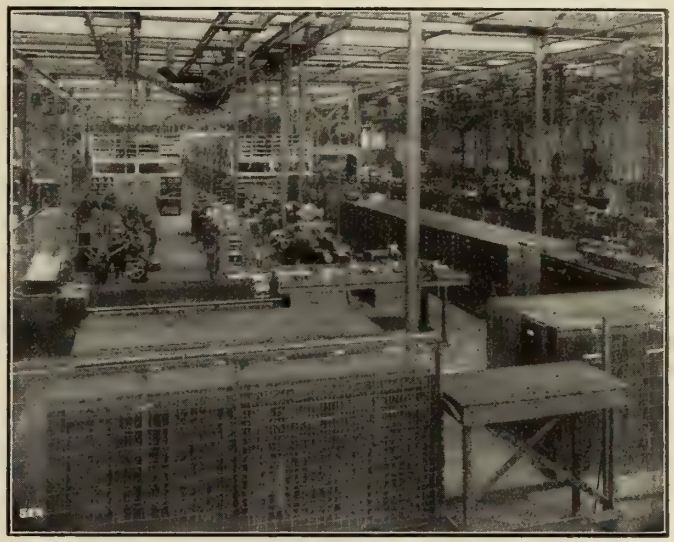
Foundry.

The foundry is located to the north of the machine shop, with which it is connected by means of an industrial track. A depressed railway siding connects with this same industrial track, over which all raw materials enter the north end of the building.

General.

The various departments are located in relation to each other in accordance with the sequence of operations, the first operation machines being at the north end of the building where the material enters. The equipment in general is highly specialized and many machines are specially fitted up for certain work. There are also many machines which have been designed and installed mainly to improve the quality of the work. Some extremely large bar work is done on automatics, the largest machines of this type taking bars 6 3-4 inches diamter. Individual motor drives are largely used, and wherever possible, the motors are mounted directly on the machines. In some cases, however, this has not been found desirable, and the motors are mounted on the ceiling directly over the machines. Next to the lathe department comes the grinding department, and next to this are the thread-milling and screw-chasing machines. In this latter section all short screw threads are milled, while the long lead screws are done entirely on automatic thread-chasing machines. Each lead screw is carefully tested for accuracy for every six inches of its length.

The Cincinnati Milling Machine Co.—Tool-Making Department.



The Cincinnati Milling Machine Co—The Tool Room.

Employees' Conveniences.

The employes' entrance is on the Columbia Road side and leads directly into the service room. Ventilated steel individual lockers are provided for each man. The wash basins are of the individual type, with hot and cold water, and in such numbers as to provide one basin for every three men. Hot water for this room, the shower baths and all the lavatories in the offices, is obtained by instantaneous heaters. The service room also contains a large toilet room, similar to those distributed at intervals throughout the plant. They are marble-lined, with marble stalls, and all the metal work is nickel-plated. The entire room is kept in a highly sanitary condition. The side walls have a space of clear glass above a line 4 feet from the floor. Adequate ventilation is obtained through a 4-inch opening all around the bottom between the side walls and the floor, and a suction ventilating fan at the top. The shower baths are for the use of all employees. They are built of marble; each space being divided into two sections; the bath in rear and a dressing room in front.

Lighting Equipment.

All the manufacturing departments are lighted by an ample installation of

Adjacent to the thread-millers are the gear cutters. This latter equipment includes a Gleason bevel gear generator and two special tooth-rounding machines shown on the right foreground. These have been designed and built to meet this company's special requirements. They have a capacity for rounding the teeth on 16 inches diameter, 2 1-2 pitch drop forged steel gears. All gears are tested on fixed centers, the theoretical distance apart, and the gears cut as closely as possible to the theoretically correct dimensions. A 20-degree pressure angle form of tooth has been adopted because of its greater strength, and the cutter for each gear is specially developed for the number of teeth for that gear. Proper running clearances between the gears are provided in the finished machine by arranging their final center distances, a few thousandths

farther than the correct figured distance apart.

Tool Room.

The tool room is located as nearly as possible centrally in the main manufacturing department and comprises a floor space of 28 ft. by 200 ft. All jigs, tools, and fixtures except some very large ones are kept in this department. Every part entering into a machine bears the number of its drawing, and this same number will apply to the pattern jig drawing, jig, tools, instruction sheet, and in fact every tool of any kind that is used in its manufacture.

The tools and jigs are listed on a card index, and each card lists all the tools of every kind used for that operation, and also gives their definite location on the shelves. These cards, bearing the part number of the piece, are arranged numerically by these numbers, thus forming a direct and quick finding system, and facilitating the immediate location of the jig itself.

This is, distinctly a storage and distributing room, neither tool-making nor repairing being done. All cutting tools, however, are sharpened here immediately upon their return from the manufacturing departments, and before being again placed on the shelves. Every tool, jig and fixture is inspected after having been used, and if in need of repairs is sent to the tool-making department. All standard small tools, such as drills, reamers, gauges, etc., are kept in cases.

Inspection.

Immediately adjacent to the tool room is the inspection department. Here all details are inspected after each machining operation. The inspection is by micrometers, clock indicators, running centers and fixed gauges. All hardened gears and clutches and similar parts are tested under the scleroscope; definite standards of hardness having been determined upon for each part. The routing department is also located here. The large charts contain a record of every piece passing through the shop, indicating which department it is in, and, therefore, which operation is being performed on it, and also the date when each successive operation must be finished. In this way absolute control is kept over the movements of every individual piece. Upon passing the final inspection, finished parts are delivered to the stock room, where they are placed on shelves and await withdrawal for assembling.

Routing of Castings.

All the large castings when entering the north end of the building are carried by the industrial track to the planing department. The planers are each driven by individual motors. A number of them have 40 ft. beds, the largest of which is 72 inches x 72 inches x 40 feet. They are provided with a variable cutting stroke, and a constant return stroke of 100 feet per minute. After leaving the planers, the castings pass to the drilling, milling, or boring departments.

Arrangement of Machines.

Machines are all grouped according to size and with regard to the nature of the work to be done on them; the larger units being located under travelling cranes. The smaller machines, facing the jib cranes to facilitate swinging large castings, are belt driven and arranged in two parallel rows.

Assembling System.

The construction of the new model milling machines is entirely on the unit system. Each group of mechanism, such as feed boxes, drive boxes, driving clutch pulleys, reverse boxes, etc., being a complete unit in itself. The final assembling, therefore, is merely the gathering of these units into a complete machine.

The machine finally arrives in the finished testing department, and here it is given a thorough test for accuracy of alignment and proper operation of all details. Every machine is given a running test under belt a specified length of time, and must do a specified amount of milling successfully before it passes inspection. A permanent record is kept of all the tests.

Adjacent to the testing department, is the final painting and packing departments. There are two doors leading to the shipping platform, one being provided with a vestibule for the protection of this part of the shop during severe weather. The doors are closed by steel drop curtain fire screens, and are entirely surrounded by circulation pipes on the hot water heating system.

The shipping platform on the outside of the building is most conveniently adapted to its purposes. The cars are placed on a depressed track, bringing their floors on a level with the platform. Three cars may be loaded at one time. There is no crane service provided, because all shipments are made in box cars.

All the shops in this new colony are models of design and efficiency for the class of work done in them, and form a delightful field of information for anyone interested in machine shop processes and machine shop building construction.

A lathe can be run at about the same speed on Monel metal as on mild steel, although Monel metal is somewhat tougher.

FORCED DRAFT SYSTEM SAVING.

THE New York Steam Laundry Co., of Montreal, recently effected a saving of $13.30 a day in their coal bill by installing a Venetian Blind Steam Blown Grate, being the Paillon System of Forced Draught. These grates replaced an automatic stoker, and were installed at the total cost of $375.00. Previously, the furnace required four tons of ¾ lump soft coal at $5.15 a ton. Now, only 2¼ tons of hard coal screenings, at $2.10 a ton, mixed with half a ton of ¾ lump soft coal at $5.15 is sufficient. It was also found that more steam could be produced, for, with the same boiler capacity there was sufficient steam to run the engine as well as the laundry. The engine had to be closed down some time ago on account of lack of steam, and a gas unit was installed. The gas unit is now used as a standby.

H. L. Peiler & Co., Montreal, installed the apparatus.

SPECIFICATIONS FOR BABBITT METALS.

THE Committee on White Metals appointed by the American Society for Testing Materials held a meeting in the Hotel Astor, New York City, on March 28th, and the following specifications for Babbitt metals were proposed:

1.—Commercially designated "Soft-Genuine," having the composition adopted by the Society of Automobile Engineers, Specification No. 17, Babbitt Metal No. 1.

2.—Alloy which is generally used in street railway service known as G. E. 17 alloy. This is closely analogous to Specification No. 18, Society of Automobile Engineers, Babbitt Metal No. 2.

3.—Intermediate grade of Babbitt metal, containing lead and copper.

4.—A true lead base Babbitt metal containing tin, which is analogous to many of the widely advertised brands of Babbitt.

5.—What is commercially known as No. 4 Babbitt, a straight lead and antimony alloy.

No.	Tin.	Antimony	Copper	Lead
1.	89%	7%	4%	None
2.	83 1-3	8 1-3	8 1-3	None
3.	50%	12%	1%	37%
4.	7%	17%	None	76%
5.	None	10%	None	90%

In connection with these alloys it was proposed to make investigations upon the heat treatment of them.

The foregoing specifications are only tentative and were suggested by the committee as a working base for further discussion.

National Fire Waste and Its Prevention

Of the many problems, each demanding more or less prompt and effective practical attention by every individual and community, none is more pressing than that of prevention of the enormous life and material losses and desolation caused by the fire demon. The author of this paper discusses the subject quite frankly, and his suggestions and conclusions are such as to command careful consideration by all of us.

COMBATING the stupendous waste due to fire, a loss that amounts to $30,000 every hour in the twenty-four each day throughout the year, was the theme of an address delivered on April 10 by Franklin H. Wentworth, secretary of the National Fire Protection Association, before the New England Foundrymen's Association, Boston.

As long as wooden cities stand, said Mr. Wentworth, disastrous fires with shocking losses of life are bound to occur. He declared, however, that the growing disposition to hold citizens personally responsible before the bar of public opinion for their carelessness is causing many of the most prolific sources of fire to disappear.

Fire Insurance Rates.

Last year the legislatures of two States, New York and Illinois, undertook an investigation of the methods and practices of the fire insurance business. This procedure found its impulse in hostility toward the fire underwriting interests; but both of these investigations developed the fact that scientific or satisfactory underwriting is impossible, and will continue to be impossible until the criminally careless fire waste of the country is curtailed. It is obvious that these investigations and the one now under way in the State of Wisconsin represent an incoherent protest against the frightful impoverishment by the fire tax. The people feel that the fire tax is too high.

It is too high! Everybody knows that it is too high, but how can it be lessened except by attacking the cause of it? This is the question that every representative body must be forced to answer. The National Fire Protection Association has members in all walks of life, and this fact brings us close to the people and to their thought currents. We are engineers and special students of the fire waste, the social and economic results of which are often clearer to us than to the underwriters themselves. It is obvious to us that insurance rates cannot be reduced irrespective of the loss ratio without forcing insurance companies who mean honestly to pay their losses to retire.

Capital investment in underwriting is not so irrevocably fixed as capital invested in public service corporations using public property or rights of way. Such investments can be controlled easily by the State, but capital invested in underwriting can easily seek other channels and withdraw if the State imposes undesirable burdens upon it; thus leaving the business world without the necessary indemnity. The hopeful result of the legislative investigations I refer to is that the conclusions reached by them indicate that the State is not to waste many years in making and unmaking laws to find out that they have begun at the wrong end. Once the people realize that they themselves are being impoverished by the fire waste, they will be led to take such precautions as will soon result in a reduction of the fire tax.

Individual and Universal Effects.

The fire waste touches the pocket of every man, woman and child in the nation; it strikes as surely but as quietly as indirect taxation; it merges with the cost of everything we eat and drink and wear. The profligate burning every year of $250,000,000 in the value of the work of men's hands means the inevitable impoverishment of the nation. What if we were to lose that sum annually out of the National Treasury, or in wheat, or corn, or cotton? A loss of $250,000,000 a year means $30,000 per hour for every hour of the twenty-four. We are burning the equivalent of a comfortable $5,000 home every ten minutes. This fearful loss, spread over the entire business world of America, is beginning to manifest its impoverishing blight. The people feel it without yet being awake to its cause. Their awakening is retarded by the prevalence of the foolish notion that the insurance companies pay this colossal tax; but how could they—and remain solvent? They are mere collectors and distributors of that portion of this tax which is represented by their policies. Half of it they never touch, it falls upon the householder direct. San Francisco and Baltimore do not pay for themselves. We in Massachusetts help pay for them. And next year San Francisco and Baltimore, risen from their ashes, may help pay for your cities or ours. There is but one way in which we can escape the periodical paying for one another, and that is for us both to begin rational building construction, and then protect what we have builded against fire.

The Conflagration Problem.

It is the ever-present conflagration hazard which makes any approach to scientific underwriting impossible. The conflagration hazard is not confined to your State, or to any. It is present in every State, every city and town. We have built largely of wood, and sooner or later we must pay the penalty unless we can find some way in which to segregate or protect our cities.

There is one way to solve this conflagration problem—not absolutely, but at least relatively. You cannot be expected to tear down your cities and rebuild them of fire-resistive material; the cities must be protected as they stand. In the heart of nearly every one there are streets crossing at right angles, along which for a very considerable distance are buildings of brick, stone and concrete. Looked at upon the map this shows a more or less complete Maltese cross of buildings which are not wooden, and which operate to divide the wooden-built district into quarter sections, and which might hold a fire in any one of these sections if they were equipped to do so. These brick and stone buildings are ordinarily valueless as fire-stops because their windows are of thin glass and their window frames of wood. At Baltimore and San Francisco the conflagration attacked such buildings easily; breaking out the panes; consuming the frames, and converting every story of these brick structures into horizontal flues full of combustible contents. Brick and stone buildings are logical and capable fire-stops if the fire can be kept out of them. The small city that will trace out its Maltese cross of such buildings and equip them with metal window frames and wired glass will immediately possess the equivalent of substantial fire walls crossing at right angles in its centre, dividing it into four sections. By such a simple, inexpensive, but yet strategic procedure many a city may save itself from the destruction which now awaits only the right kind of a fire on the right kind of a night.

Restriction of Fire Range.

I have referred in this plan merely to the smaller cities, but it is obvious that this form of protection is equally imperative in the brick, stone and concrete districts of all large cities where great values are housed in close proximity. Fires in the large cities entail an enormous waste because of the great values assembled there. We must come eventually to the equipment of all commercial, factory and office buildings with metal window frames and wired glass. This will mean the abolition of the conflagration hazard in our cities. Fires will then be unit fires, extinguished easily by a competent fire department

within the building in which they originate, for the protection of window openings not only prevents fire from entering but prevents fires from issuing out of the burning building. We may expect an occasional exceedingly hot fire to break down the defences of an adjoining building, but it is obvious that a conflagration could not get under way among buildings of fire-resistive construction with properly protected window openings.

Sprinkler Equipment a Necessity.

Having thus fortified city buildings one against the other, extensive fires within individual structures can be prevented by the use of the now well established automatic sprinkler system. The automatic sprinkler applies the water without the help of human agencies while the fire is still incipient. It will operate in a dense smoke as well as in a clear atmosphere. It will not throw excessive deluges of water in wrong places, as the fire departments are continually forced to do. With our window openings protected and our buildings equipped with such extinguishers the conflagration hazard in mercantile districts will be eliminated. There will then remain for consideration our immense residence districts constructed almost wholly of wood surrounding the mercantile centres, like fagots around a funeral pyre. We can lessen the loss here by the abolition of the use of wooden shingles.

Abolition of Shingle Roofs.

The prohibition of the shingle roof, which is now generally recognized as a conflagration breeder, is to-day almost universal within city fire limits, and from the more enlightened communities it is excluded altogether. Burning shingles can be carried great distances by the wind or draught of a conflagration, and when they alight in their turn upon other dry shingles, they make fearful havoc. The natural anarchy of the American temperament does not readily respond to admonitions to correct its careless habits and recognize its public responsibilities; but our common impoverishment by the stupendous proportions of the fire tax is beginning to impress itself upon us so forcibly that even the most heedless of us is forced to give some thought to the common good and the common safety.

It will not be necessary to remove all shingle roofs immediately. An effective city ordinance might require all roofs constructed in the future to be of incombustible material, and that all roofs which shall hereafter require repair to the extent of one-third of their area shall be replaced with incombustible roofs. The modern shingle is thin, and the machinery which now makes it leaves a fuzzy surface which, after a period of draught, becomes like tinder. Without shingle roofs, flying brands would not be carried over the brick centres of the city by the wind.

People's Habits Require Correction.

Outside of the abolition of the shingle roof, we must look for the protection of our homes to the corrected habits of our people. We must look carefully after the heating apparatus of our homes, giving them the constant and necessary attention demanded by receptacles containing fire. The building of proper flues and chimneys is especially necessary in connection with residences. The most vital matter in the home, however, is the proper use of the match. Every match is a potential conflagration, as every fire is of the same size when it starts. No match should be admitted inside a house except the variety which ignites only on the box. Hundreds of women and children are burned to death in America every year by the type of match that will ignite on any surface. These matches are allowed to lie indiscriminately about the homes. Small children are imitative, and if they can secure such a match, will attempt to ignite it, generally setting fire to their clothing. No father who has proper regard for his family will allow a "strike anywhere" match in his home. The observation of the precaution I have indicated would mean an almost immediate reduction of the fire waste by perhaps fifty per cent.

PHILOSOPHY OF LEARNING A TRADE.

To make a good living; to have a happy family; to make preparation for hard times; to wear overalls in the shop with the same dignity as good clothes are worn on Sunday; to be confident you are laying a sure foundation for any future success; to feel that you are master of your work and that you share the creative spirit; this is the wholesome philosophy of learning a trade.—Milton P. Higgins in "Grits and Grinds."

Fire-Fighting Agencies.

There are other matters, however, to which we must now give proper thought. Among them is the best use of the fire-fighting agencies which have been established, and which are maintained at a great cost by our people.

The mental habits of a people are a vital factor in affecting social progress. It is the mental habit to assume that fire departments are maintained for the exclusive purpose of extinguishing fires. It is obvious, however, that fire departments have large possibilities for service in preventing fires; a service which is, I regret to say, yet largely potential. Every fireman, from the chief engineer down to the drivers and pipe men, should be regularly detailed for inspection service. Three or four hours a week should be spent by each man, going into basements, attics, courts and alleys, keeping down accumulations of rubbish—which spring up over night and locating the storage of inflammable oils and explosives. This would keep the city clear of its most persistent fire dangers. Every fireman should in turn cover every section in the course of six months. One would thus check up the inspections of the other, and local conditions would become a matter for educative conversation about headquarters.

Education of Fire-Fighters.

There is, however, a most important result to be achieved by such an inspection system over and beyond keeping the city clean; that is the education of the fire-fighters in the exact physical character of the city. To know exactly which passageways are open and which are closed; to know which are fire walls and which are not; to have a mental picture of the exposures, the windows, the roof openings, the cornices, and all the other physical details important in fire-fighting, would so heighten the team work of a department that, like expert swordsmen, they could make their thrusts without loss of time, straight at the vulnerable part. There are a few cities in America where this practice, partially in effect, has already demonstrated its singular efficiency. The citizens of every town and city in the country should demand a like service from its fire department.

Public Awakening to the Issue.

The American people are not dull in comprehension nor, are they slow to act, once the necessities of a situation are made clear to them. The awakening of the present year, manifested by the observance of "Fire Prevention Day" in many States; by the appointment of fire marshals and the amendment of the fire marshal laws; and by the teaching of the fire hazard in many public schools, indicates that we as a people will not much longer tolerate our pitiful impoverishment by the fire waste. It is true that so long as our wooden cities stand they must occasionally suffer disastrous fires with, oftentimes, shocking loss of life; but with the growing disposition to hold our citizens personally responsible for their carelessness before the bar of public opinion, many of our most prolific causes of fire will disappear.

Our civilization grows daily more complex. Every man's life is becoming

more inextricably linked with the lives of others, hence, an injury to one is increasingly an injury to all. Out of a proper realization of these facts is coming a larger sense of civic responsibility. As citizens of a common country and brothers of a great national family we may some day evolve a civilization in which there shall be no waste, and in which the thought of the common good shall be the profoundest impulse in the hearts of our people.

THE SHARING OF KNOWLEDGE AMONG ENGINEERS.

By Chas. T. Main, Boston.

AN engineer possessing information not of a private nature and of benefit to the profession in general, should be broad enough in his outlook to publish same for the benefit of his brother craftsmen. He will find on looking at the matter even from a selfish point of view, that he will not be the loser, for it will bring him into greater prominence and call attention to the fact that he is the man to be employed or consulted in work involving this particular experience.

Such men should always be glad to impart to the younger generation any information available. They should never stand in the way of a younger man improving his position, even if it is at a sacrifice to their own interests. If the younger man has an opportunity of obtaining a better position elsewhere, it should either be met with equal consideration of some sort or he should be allowed to make the change.

Younger men, on the other hand, should be governed by a feeling of loyalty to their employers and profession. This should deter them from taking undue advantage of circumstances, which for the time being, might temporarily enhance the value of their services. The relation of an engineer and his assistants should at all times be governed by a spirit of fair play on both sides.

CANADA'S SUPPLY OF COAL.

CENTRAL Canada is constantly within measurable distance of a coal famine; nor are the conditions which may precipitate such a famine in any considerable degree within the country's control. This is due to the fact that all Eastern and Central Canada is dependent on the Pennsylvania fields for their supplies of anthracite coal. In view of threatened strikes of the Pennsylvania miners, the situation becomes of unusually grave importance to Canadians. It is only when such strikes occur that the public actually realizes how dependent it is upon supplies of United States coal. Again, very few seem to realize the fact that the supplies of United States coal, both anthracite and bituminous, may be entirely denied us at any time. Mr. George Otis Smith of the U.S. Geological Survey, says: "Let us keep our coal at home, and with it manufacture whatever the world needs." Should this happen, can we say that we are prepared to get along without it?

Dependence on United States for Anthracite.

According to a recent estimate, anthracite coal in the United States will be exhausted in less than two hundred years. Long before that time the cost will increase and the United States Government will see to it that the coal is not exported, but kept at home for its own needs. Let us see to what extent United States coal is sold in Canada. Enquiries sent out by the Commission of Conservation show that the following Provinces are supplied with anthracite coal from the United States:

Province-Cost to Consumer.

Nova Scotia	$6.50 to $7.00
Cape Breton	6.50 to 8.00
Prince Edw. Island	6.00 to 6.50
New Brunswick	7.00 to 8.00
Quebec	6.50 to 7.50
Ontario (East of Port Arthur)	6.00 to 7.75
Ontario (West of Port Arthur)	8.00 to 11.00
Manitoba	11.00 to 12.50
Saskatchewan	12.50 to 15.00

Our Bituminous Coal Supply.

With regard to bituminous coal, Ontario, west of Cornwall, is supplied entirely from the United States. Owing to the low freight rate, Nova Scotia cannot compete with United States coal west of Cornwall. The bituminous coal consumed in Manitoba is almost entirely from the United States, although coal mined in the Crow's Nest and Lethbridge districts finds a ready market in Western Manitoba.

From the above, it can be seen that one of the most important questions we have in Canada, at least in the Province of Ontario and the Prairie Provinces, is the question of fuel. The fuel for the Prairies Provinces will necessarily be supplied in the form of coal and briquettes from mines in British Columbia, Alberta and Saskatchewan. This, however, does not apply to the Province of Ontario, and for economic reasons stated before, Nova Scotia coal cannot find a market in Ontario.

Peat as a Substitute.

The other sources of heat, light and power are peat, wood and hydro-electric power. Of these, peat and hydro-electric power only can be considered as substitutes for coal. With regard to peat, the Mines Branch of the Department of Mines has demonstrated the fact that peat can be successfully and economically used for fuel and power purposes. Estimating the cost per ton of peat at the bog, $2.00, and the cost of soft coal $4.00 per ton; then in car lots f.o.b., the fuel cost per brake horse-power year (3,000 hours) would be as follows:

Peat producer gas plant*	$ 7.50
Coal producer gas plant	9.00
Steam plant	36.00

Mr. B. F. Haanel of the Mines Branch, in commenting on the foregoing, states that when peat is manufactured on a large scale with machines provided with mechanical excavators and other labor-saving devices, the cost per ton of peat at the bog will be considerably less than $2.00.

While power generated from peat may be successfully used in certain localities in different parts of the country, owing to the low cost of hydro-electric power and the abundance of water-power, the chief substitute for coal which will make Ontario almost entirely independent of United States coal, will be hydro-electric energy. The Hydro-Electric Power Commission has done much to further the use of hydro-electric power by distributing to different centres, and vigilance must be exercised to see that the sources of this energy are not disposed of in such a manner as to deprive the people of power at reasonable rates.

ROPE CAPACITY OF A DRUM.

THE rule used by the A. Leschen & Sons Rope Co. for computing the rope capacity of any sized drum is as follows:—Add the depth of flange in inches to the diameter of the drum, and multiply this result by the width (out to out) of the drum. This product is then multiplied by the figure below corresponding to the size of rope used:—

1/4 in.	4.16	1 3/8 in.	.138
3/8 in.	1.86	1 1/2 in.	.116
7-16 in.	1.37	1 5/8 in.	.099
1/2 in.	1.05	1 3/4 in.	.085
9-16 in.	.828	1 7/8 in.	.074
5/8 in.	.672	2 in.	.066
3/4 in.	.465	2 1/8 in.	.058
7/8 in.	.342	2 1/4 in.	.052
1 in.	.262	2 3/8 in.	.046
1 1/8 in.	.207	2 1/2 in.	.042
1 1/4 in.	.167		

Mr. E. F. Bradley has been appointed sales manager to the Canada Wire & Cable Co., Ltd. Mr. Bradley has been identified for some time with the Canadian General Electric Company.

The Modern Boiler Shop and Its Layout and Equipment*

By H. C. Meinholtz

The author of this paper deals in an easily intelligible, yet comprehensive, fashion with what might be termed the "sound first principles" to be observed by those who would have a boiler and tank building plant designed and arranged to produce quality and quantity work at minimum cost.

THE planning of a boiler shop involves careful study, principally on account of the variety of work that is, or may be done in a shop fitted with modern appliances. We cannot calculate on building one particular class of boilers, smoke stacks, etc., but must consider also the general line of tank work, smoke flues, flumes and even structural work that must, of necessity, be done in addition to the regular line of boiler work. If a manufacturer has a particular line of work in mind, his principal object is to fit himself with a shop and tools to fabricate such specialty at a minimum cost.

Choice of Site.

The selection of a proper site for the erection of a shop is very important, and as every boiler manufacturer is expected to attend to repair work besides the building of new work, the site available often determines the arrangement of building and machinery. In order to take advantage of sundry repair work, it is necessary to locate near the manufacturing centers of the large cities. On the other hand, a strictly manufacturing plant may be located on the outskirts or in the suburbs of thickly-populated centers.

Experience teaches us that the better and more intelligent class of mechanics favor living in or close to the large cities, principally because they are offered more opportunities to learn what work is accomplished by other men engaged in the same occupation, and they can also provide better and cheaper means of educating and entertaining their families. While it is true that in a community with an established manufacturing plant, there should be no scarcity of labor, yet we must admit that at certain times a boiler manufacturer is seriously handicapped by a scarcity of work to keep all his men employed advantageously, and at such times a manufacturer located close to the labor market has a decided advantage.

Constructional Detail of Building.

A modern boiler shop should be of fire proof construction. All woodwork should be avoided as far as possible. The walls, columns, girders and roof should be built of non-combustible materials, and a maximum of natural light and ventilation should be supplied to the workmen. The most serviceable shops have brick or concrete walls with a concrete roof supported on steel trusses. The roof should be reinforced with heavy steel wire and covered with composition or prepared roofing material Ventilators should be provided to carry off the smoke and fumes from the open fires, for hoods such as are usually placed over the fires and heating forges do not as a rule provide sufficient means for carrying off the products of combustion. Window frames, three-sash high, are desirable, as two-thirds of the window opening is thereby available for ventilation. All buildings should be built of ample height and at no point should the distance from the bottom of the roof trusses to the floor level be less than 20 feet.

Floor and Machinery Layout.

When possible, the shop should have a main erecting floor of suitable width and length, and the craneway should extend the entire length of the shop. The crane rails should be of sufficient height to permit of transferring work from one part of the shop to another without disturbing the work on the floor.

A lean-to should be built on both sides of the erecting floor, and the machinery should be placed in these to preserve a clear and unobstructed erecting floor. Each lean-to, if 40 feet wide, will be of ample size for the punches, shears, rolls, etc. When planning the location of the various machines, the loading and unloading facilities must be considered, since the tonnage of steel passing through a boiler shop is enormous. It is essential that the unloading of raw materials from cars be done at a different point than the loading of the finished product, for in this manner only can a regular route of travel for the work through the shop be established.

Proper racks should be provided so that immediately upon unloading plates from the cars, they can be properly assorted. Racks in which plates are placed in a vertical position are preferable, as less floor space is occupied than when the plates are stored flat. The layer-out should be stationed close to the plate racks and the splitting shears should be close at hand for cutting plates. All the punches should be placed in line, and following these, should be located the bevel shears for planers for beveling the edges of the sheets. Next to these, the rolls should be installed. At this stage of manufacture, the fitting-up is done, and space should be provided for machines to ream rivet holes and to prepare the plates for the riveter. In a 40-foot bay or lean-to, the splitting shears, bevel shears and planers may be set opposite the punches.

The trusses supporting the roof over the lean-to should be of ample strength to support a runaway for small, hand-operated cranes. In a 40-foot bay, parallel runaways, 20 feet wide, should be provided, and so arranged that one set of cranes will pass the other. The advantage of such an arrangement is apparent, as each machine may have its own crane, the operator on any one machine may remove his work and transport it to another machine without interfering with his neighbor. These cranes also can be provided with interlocking devices so that a continuous crane, 40 feet long, can be made of the two shorter travelers.

Owing to the fact that the sharp edges on plates are liable to injure the workmen, it is advisable to have a clear floor all around the machines. Riveters should be placed in the lean-to commanded by the cranes and they should be so located that the work from the riveter can be reached by the main crane serving the erecting floor.

Machine Drives.

All punches, shears, rolls, etc., should be operated by individual motors of like type and speed. By selecting a few sizes of one type of motor, and by carrying an extra motor of each size on hand, no serious delays can occur, since a spare motor can readily be used to replace a defective machine and no fitting of base plates or change of gearing is required. When no extra motors are at hand, often a motor from another machine not in use may be utilized.

Flanging Department.

Flange shops should be separated from the main shop, wherever possible, but should be located so that the work may be passed from one shop to the other at a minimum of expense. In addition to the customary flanging machines, a large furnace should be provided so that all flanger work may be heated, straightened and annealed.

*From a paper read at the Boiler Manufacturers' Association Convention, New Orleans, 1912.

The Power Plant.

The power house should be isolated from the main and flange shops. In addition to the engine and air compressor, the hydraulic pump and accumulator should be placed in the engine room, so that all power units may be directly in care of the engine room attendant. The hydraulic riveters, punches, flanging machines, etc., should be arranged in such a manner that the distance of travel of the water through the pipes supplying the various machines is reduced to a minimum. Proper shock absorbing valves should be provided as well as safety appliances to prevent over-pumping the accumulator, and a special check valve should be placed in the supply pipe to the accumulator so that in case of a failure in the hydraulic pipe, the accumulator will not drop suddenly and injure the machine or buildings.

The hydraulic pump should be fitted with a speed controlling device so that a fixed speed of the pump cannot be exceeded in case of a break in the pressure line. It has been the custom to equip shops containing machines that are of necessity operated at variable speeds, with direct current generator and motors, but for operating a boiler shop we can safely consider alternating current machines since the variations of speed that may be obtained with alternating current motors are quite ample for all purposes.

Test Department.

A special section of the shop, preferably close to the loading or shipping track, should be set aside for a test floor, and a system of drains should connect the floor with a reserve or storage cistern.

General.

While we are considering a strictly fireproof shop, we must, nevertheless, provide the necessary means to successfully fight a fire. An adequate number of non-freezable fire plugs should therefore be installed with the necessary hose and nozzles.

A separate building should be provided for the storage of oils, paints, etc., and only small quantities of these, required for immediate use, should be permitted in the shop.

In the majority of plants no provision is made for heating in cold weather. It is a mistaken idea to expect men to keep themselves warm by work, as a great many of them are employed on jobs that do not require a sufficient amount of energy to enable them to do so. Means, therefore, should be provided to maintain a shop temperature of about 50 degrees Fahr. in severe weather.

EFFECTIVE STRESS IN BELTS.

IN a recent issue of Zeits, des Vereines Deutscher Ingenieure appears an account of tests on the limits of effective stress in belts of various materials. An abstract of the article appears in the April Journal of the American Society of Mechanical Engineers. Such tests require a large expenditure of time, because overloading of a belt can be discovered only from the appearance of a permanent elongation, and an identical elongation is also found in a new belt which has not yet reached its state of resistance. Since, however, several hours are required for a belt to reach that state, there is always a danger, in short tests with new belts, of taking phenomena of the state of resistance for those of overload.

Tests of Link Belts.

The tests were made on two link belts of equal width, but unequal thickness, made up of links pressed out of specially prepared fibre, and provided with leather rims. The tests show that at a speed of say 50 feet per second, the total stress on the tight side of the belt must not exceed 166 lbs. per inch, but at higher speeds may go as high as 193 lbs. per inch of width of belt. Link belts have been introduced because they combined the strength of double with the flexibility of single belts, and gave strong belts which could be used on pulleys of small diameter. These tests have shown that for speeds up to 65 feet per second, link belts are far superior not only to single, but even to double leather belts; but at higher speeds, the centrifugal tension in the heavy link belt decreases the allowable useful load very materially, and at speeds over 98 ft. per second, link belts cannot be economically used at all.

Tests of Leather Belts.

For speeds up to 50 feet per second, the total stress on the tight side of the belt did not exceed say 126 lb. per inch of the width of the belt, while for a speed of 98 feet per second, the total useful tension rose to 143 lbs. per inch of width of belt.

It is often asserted that belts which have the hair side to the pulley, last longer than when turned with the flesh side to the pulley. Tests made by the author show that in belts turned with the hair side to the pulley: (a) the tension ratio or ratio between the tension on the tight side and that on the loose side hardly exceeds 2, while in belts running with the flesh side to the pulley, it can exceed 3; (b) the highest allowable tension is more than 12.6 lbs. per inch less than in the case of belts with the flesh side toward the pulley. Again, the speed cannot be made more than 98 feet per second, against 164 feet with belts having the flesh side next the pulley.

This shows that it is in every respect disadvantageous to let the belt run with the hair side toward the pulley. A belt running in that way probably wears out sooner, because, as was pointed out by C. O. Gehrkens, such curvature reverses the way in which the hide grew on the animal.

Tests of High Speed Belting.

A double cemented leather belt, 1.8 inches wide, stood very well a total tension on the tight side of 370 lbs. per inch at 196 feet per second, and broke only when the tension rose to say 530 lbs. per inch. The allowable useful stress (kn) can be deduced from the formula:—

$$kn = (kT - kf) \times \tfrac{3}{4},$$

where kT is the total stress on the tight side, and kf the centrifugal tension.

In the tests with woven belts it was found, that, as the speed of the belt transmission increased, the allowable useful stress diminished owing to the influence of the belt fastening, which at speeds from 81 to 98 feet per second caused such vibration and uncertainty of run that it proved to be impossible to exceed the speed of 98 feet per second. The influence of the fastening is due to the following causes: (a) Because the centre of gravity of the fastening describes on the pulley a semicircle, an additional centrifugal tension is developed equal to

$$kf = \frac{G}{bl} \cdot \frac{v^2}{g}$$

This additional centrifugal tension is thus a function of

$$\frac{G}{bl},$$

or weight of unit area of the fastening, and that indicates the advisability of arranging the fastening in such a way that its weight be distributed over as large an area of the belt as possible; (b) The rotation of the fastening in coming on and off the pulley produces in it a moment of torsion which in its turn produces in the belt an additional centrifugal tension. This tension becomes negligible if the fastening is made of flexible steel bands; soft steel bands lasting longer than hard ones.

In casting brass in sand if the gate breaks off in the mold, it usually indicates that the metal is not good. Such a breakage shows that the metal is red short and breaks while cooling. The difficulty may be caused by the presence of sulphur, antimony, arsenic or other foreign elements in the metal. Bronze or composite acts in the same manner as brass.

Prominent Features of Forge Practice in English Shops, III.

By Joseph Horner

The writer is well and favorably known through his contributions to the editorial columns of the leading technical journals of Great Britain and the United States. Concerning Canada, he is no stranger, having on previous occasions furnished highly instructive information to readers of Canadian Machinery on important developments in mechanical engineering practice. The subject of the present series of articles will be found extremely interesting, enabling, as it does, a close comparison between British and Canadian methods to be made, and perhaps profitable hints extracted.

THE third large group of forged work comprises that which is made in plate or from wide bars by bending, flanging, setting, welding. This includes very massive articles. In England the hydraulic press is employed chiefly for this class of work. There are several designs, varied to deal with different classes of operation, or of operations done in succession to avoid moving the work about, in order to finish two or three operations at one heat. The differences are those of ram arrangements; one, two, or three rams being fitted. The simplest press has one vertical ram moving downwards. Many presses have two; one descending from above, the other ascending from below. A goodly number have, in addition, a third ram moving horizontally outwards from the frame. The utilities of this last type are very great, enabling many intricate forgings to be done at one heat which if attempted on the simpler presses would require two heats.

The powers of useful presses for this class of work range from 50 to 200 tons, and the lengths of stroke from 9 to 30

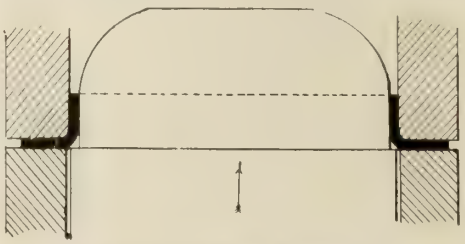


Fig. 23.—Forge Practice.

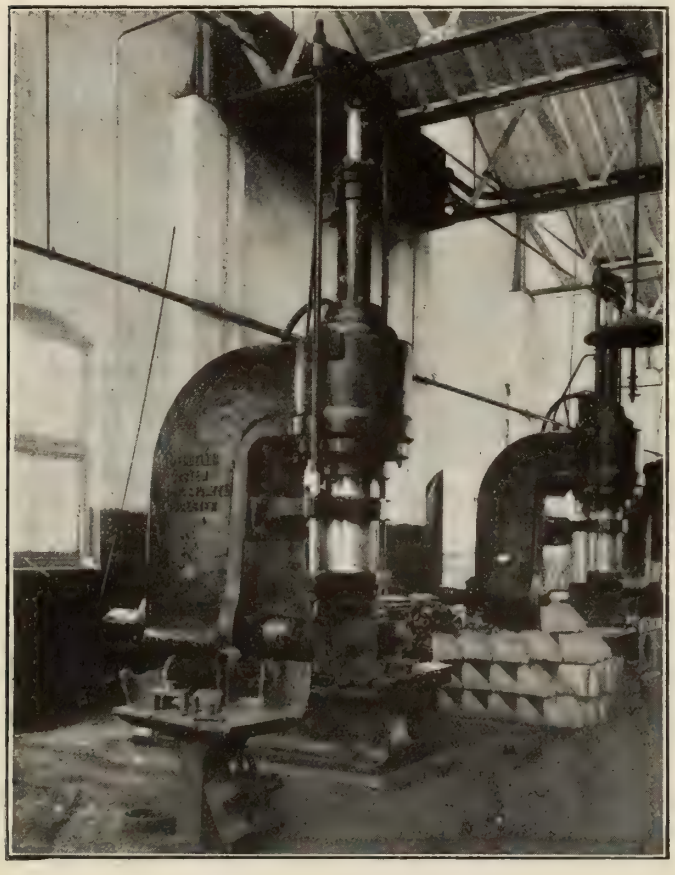
inches. The water pressure is 1,500 lbs. per square inch. Two kinds of machine are built, the older being slower and less economical than the newer, and having the pressure water throughout the entire stroke. In the newer types, water from a tank acting by gravity moves the ram rapidly into contact with the work, after which the accumulator water is brought into action to impart the pressure. An intensifier is also included for the more powerful presses.

Pressed Plate Work.

Work which is pressed in plates involves an entirely different set of conditions from that which is forged by hammer blows. There is little reduction, often none at all in thickness of widths, but a good deal of bending, and some welding and final setting. The dies are massive; being built of cast-iron and steel. Shapes are stamped out by steel dies screwed to bodies of cast iron. The kind of work for which these presses are properly adapted is of the same class for which the bulldozer is used. They bend,



Forging Press in Swindon Shop.

flange, punch and weld in dies, but are not so suitable for heavy bar work as are the steam and power hammers. Hydraulic presses are, however, nearly ubiquitous in the railway wagon shops for preparing the iron and steel work of wagons and carriages.

Work of this kind when done by the ordinary methods of the forge, entails welding and riveting, or setting and bending blocks, and is performed by the platers and not by the smiths. By comparison with these methods, the time saved is enormous. In some cases, these forgings take the place of castings with much reduction in weight and freedom from risk of fracture. Many examples might be given, but they would entail numerous drawings. The photographs show forging presses and dies taken at the Swindon Works of the Great Western Railway, and will give a good idea of the nature of the work done. The work regularly done includes rings, spring shoes, brake parts, spring buckles, shoes of various kinds, draw bar plates, covers, buffer sockets, axle guards, etc.

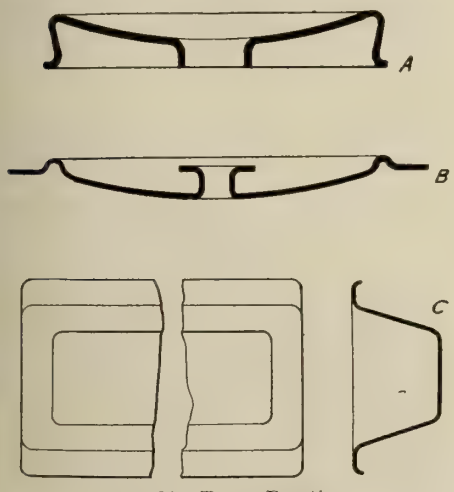

Fig. 24.—Forge Practice.

Possibilities of Pressing.

The possibilities of pressing may be inferred from a few selected illustrations of the work. The drawing, Fig. 22, is a rather common example of simple work. It shows how a manhole is pressed in ordinary practice; idential methods being adopted for the rings for uptakes of vertical boilers, in hand holes, tank openings, and similar articles. The plate cut to the right diameter on rotary shears, in the lathe, or punched out in small diameters, is laid on a die and pressed into the opening of the latter with the punch attached to the top either of the press or of the hammer. One movement suffices to complete the job. Fig. 23 illustrates another method practised under the hydraulic press. The upper and lower portions of the dies secure the flange while the lower die moving upwards turns the plate to shape within the upper die.

Fig. 24 is a group of forgings all made in dies in hydraulic presses. The plates are heated in reverberatory furnaces and pressed in massive cast-iron dies. (A) is a piston, (B) a cover for brake cylinders, each done in several stages, and (C) a trough or manger about 5 feet in length, stamped in one piece of plate. The article (A) is stamped first with the outer flange plain. The setting is done afterwards in stages by the horizontal ram of the press actuating a die-block of suitable shape. In the forging (B) the flange and neck are both prepared separately and welded to the plate. The welding is done between divided dies before the plate is pressed to its dished form; this being done at one squeeze, between top and bottom dies; the top die having a recess in the centre large enough for the flange and neck to pass up into.

ROPE DRIVING.

IN a paper read by Mr. R. E. Hart before the Association of Engineers-in-Charge (England), the author defined the requirements for a successful rope-drive.

The main features of an ideal rope-drive are that the diameter of the pulleys shall not be less than thirty times the diameter of the rope used, and the driving and driven pulleys shall, if possible, be of equal diameter; but where this cannot be arranged, their ratios

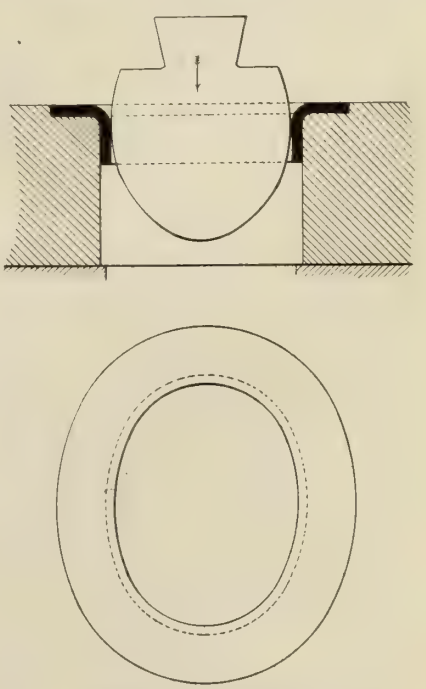

Fig. 22.—Forge Practice.

should not be greater than 5 to 1. The distance between the pulley faces should, if possible, be not less than 25 feet, and the drive should be horizontal, with the slack side of the rope on the top. The

speed may be from 2,000 feet to 4,000 feet per minute, but if too low the ropes are apt to slip, and if too high, the action of centrifugal forces affects the efficiency.

There should be a distance of from 4 to 6 feet clearance under the ropes, and these must, of course, not rub on anything. An allowance of 2 or 3 inches clearance between the bearing foundations and the sides of the pulleys must be made so as to leave room for the ropes to be put on to the pulley. The pulleys must also be accurately in line, well balanced, and the grooves exactly alike.

All gears between the prime mover and the rope-drive should, if possible, be avoided; the ropes should be kept dry, properly lubricated, and not too tight. They should all be put on at one time, and the full load applied to them as soon as possible after they are in place. Carrier pulleys, rollers, and angular drives should be avoided as much as possible.

Type of Rope.

Regarding the two types of rope generally used—namely, three-strand and four-strand—the former can be made more pliable than the latter, and it is also stronger; but these advantages are more than counterbalanced in the four-strand rope, because, compared with the three-strand, it stretches very much less, and has a larger surface in contact with the pulley grooves. It is also capable of a stronger splice. A well-made four-strand rope is, moreover, nearly as strong as a three-strand, but it requires more skill to splice it. The general opinion, now, is that cotton is the best material to use for driving-ropes, and Egyptian cotton, though a little more expensive than American, is generally preferred.

THE PUBLIC'S DEBT TO LABOR.

WHEN we review the field of human endeavor, we find that many of our national glories have been produced at an unnecessary sacrifice of human labor. To the laborer and the mechanic belongs the honor for producing the vehicles in which we ride, the clothes we wear, the buildings in which we live and work, and the machinery that plays an important part in everyday life. Still the lives of these men are considered of little value in the mad rush to excel in commercial competition. In the race of the industrial juggernaut, human lives are maimed and crushed, figures stunted and deformed, bodies poisoned, women made widows and children orphans.

Capital has become indifferent to the interests of labor in many cases, but thanks to measures instituted by organizations that have the welfare of the laboring classes at heart, remedies to eradicate many evils have been brought into action of late and it is to be hoped that such work may continue until a standard that insures the fullest protection possible has been reached.

More efficient guarding of machinery in factories is required, and in this connection, an increased demand for more factory inspectors and a more efficient organization of the factory inspection force is desired. There is great need for better ventilation in our factories and steps are being taken in the introduction of measures that will make better ventilation compulsory in buildings where workmen are congregated.—Nat. Coml.

CONCENTRATION OF ENERGY.

A SAVING of about 200 million tons of coal annually is estimated by Mr. Samuel Insull as the result of a general concentration of energy production in the United States. When addressing the American Institute of Electrical Engineers, Mr. Insull made further calculations which ought to encourage and inspire the growing number of engineers who are bestirring themselves to awaken public opinion on the question of fuel economy. In New York, the total load on several systems of generation is 678,000 k.w. If they were consolidated, the diversity factor would come into operation to reduce this amount by 47,000 k.w. In Boston, Mr. Insull estimates that if the lighting and traction loads were dealt with under one system the maximum demand would come down from 111,200 k.w. to 95,400 k.w. Further great economy would, of course, result if the steam railway services were brought into the scheme.

The ensuing discussion was enlightened by contributions from some of America's foremost authorities, and one of the most remarkable was that of Professor Dugald Jackson, who declared that such concentration of energy would be necessary to maintain the cities of the future as suitable places for habitation.

STEEL PRODUCTION IN THE UNITED STATES.

ACCORDING to statistics received from manufacturers by the American Iron and Steel Association, the production of all kinds of steel ingots and castings in the United States during 1911 amounted to 23,675,501 tons, as compared with 26,094,919 tons in 1910; this latter being the largest total recorded in that country for one year. The total of 23,955,021 tons in 1909 was the nearest approach to 1910. The 1911 production was made up of 23,029,479 tons of ignots and 646,022 tons of castings; it included 7,947,849 tons of Bessemer, 15,598,650 tons open hearth, and 129,002 tons of crucible and other steel. It is noteworthy that the production by the electric process amounted to 29,105 tons, as against 52,141 tons in 1910. In 1911 there were nine electric plants in operation; one in Massachussets, three in New York, three in Pennsylvania, one in Indiana, and one in Illinois.

SWEEP MOULDING AN OIL TANK IN GREEN SAND.

By J. H. Eastham.

THE article entitled "Sweep Moulding an Oil Tank in Green Sand," which appeared in our May issue, was incomplete, to the extent that Fig. 6, showing the finished mould was omitted. It is here shown, and in conjunction with it, the last paragraph of the article has been reproduced as follows:

The cross section view of the finished

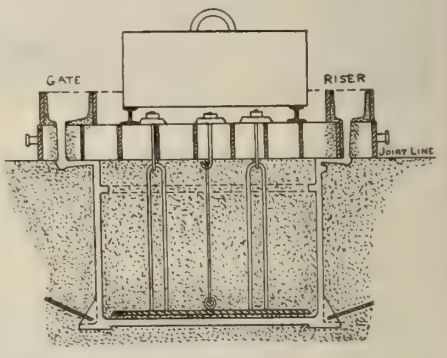

Fig. 6—Sweep Moulding an Oil Tank in Green Sand.

mould, at Fig. 6, shows type of runner and riser adopted, hook bolt and lifter arrangement, straight irons over and under the flange, and seating brackets.

AMERICAN ELECTRO-CHEMICAL SOCIETY.

Mr. William Lash Miller, professor of chemistry at the University of Toronto, has been elected president of the American Electro-Chemical Society. To a Canadian this is a signal honor, in view of the fact that he will represent the American Electro-chemical Society at the Congress of Applied Chemistry, which meets in Washington next September, on the invitation of the President and Government of the United States.

At this meeting, which is held every five years, there will be industrial chemists from all over the world. This will be the first time the society has met in America, the last meeting having been held in Rome.

U.S. Committee Report on Systems of Shop Management

The United States House of Representatives in the early fall of 1911 appointed a committee to investigate the various systems of "shop management," which had been propounded and introduced into the practice of a number of private manufacturing concerns and to a limited extent into several Government works. The thoroughness of the investigation and the reasonableness of the conclusions arrived at, will, we are sure, be generally approved.

SCOPE OF THE INQUIRY.

YOUR committee appointed under House resolution 90, adopted August 21, 1911, respectfully submits the following report:

By the provisions of the resolution under which it was appointed, your committee was directed "to investigate the Taylor and other systems of shop management, which investigation shall include its applicability to Government works, its effect on the health and pay of employes, its effect on wages and labor cost, and such other matters connected therewith as may give a thorough understanding of the results of the installation of this system."

General Observations.

We have examined a number of witnesses relative to the various systems of shop management which have been worked out and are being introduced in a limited number of establishments throughout the country, but we have given special attention to an investigation of the Taylor system, because we found that this system is being introduced in part in two Government arsenals and its extension into other Government plants is being seriously considered by the officers of the ordnance bureau of the War Department. All of these systems, including the Taylor system, have become known by the general term "scientific management" and are referred to as such throughout the hearings, a copy of which accompanies this report.

A great amount of good work has been done by Mr. Taylor and others in working out the details of scientific methods of shop management, but neither Mr. Taylor nor anyone else has presented to this committee a system so complete and perfect as to justify a recommendation that it be imposed in any Government shop.

Gradual Evolution Desirable.

Any radical change in factory management should be a gradual evolution out of that which has preceded. The present systems, or lack of systems, with their good and bad points, are themselves the result of long evolutions. No drastic or radical change in them should be suddenly or even quickly imposed by fiat from above. Men have become accustomed alike to the good and bad that are in the systems under which they work. They know and approve the good; they know how to combat the evil. They are naturally and properly suspicious that motives purely selfish may be behind the sudden change. Confidence is a plant of slow growth.

Neither the Taylor system nor any other should be imposed from above on an unwilling working force. Any system of shop management ought to be the result of mutual conference and mutual consent, and that takes time. Government in a mill should be like government in a state—"with the consent of the governed."

It appears to your committee that no one can seriously object, and as a matter of fact, no one has objected, to any system which so standardizes and systematizes the work to be performed that a greater amount of production is secured with the same expenditure of labor. Employer and employe alike and the public generally are interested in securing the largest amount and the best quality of production that can possibly be secured by the amount of labor expended. All men have a mutual interest in the accomplishment of that end. It is only when it comes to a division of that which has been produced that their interests diverge. It, therefore, follows that any system of management, which has a tendency to destroy the power of employes, individually or collectively, to secure the equivalent of the production which properly belongs to them, must be looked upon as being dangerous to the welfare of the community at large.

Efficiency must not be had at the cost of the men, women and children who labor and who should be the primary beneficiaries from it. We should study how to produce the best results in output while also producing conditions to make the most efficient men and women to produce that output. This must be done by conserving in every way not only their health, physical and nervous vigor, but by creating such conditions as will permit them to work out their own happiness and contentment through wages which will enable them to live in such a manner as to maintain their own self-respect, and with sufficient leisure to enjoy the refreshing influence of mental and moral recreation.

The Taylor System.

The Taylor system of shop management may be divided into three general heads: Standardization, systematization, and stimulation. Efficiency may be gained in whole or in part by any of these ways; by any two of them, or by all three combined. Any or all, however, may be carried to an extreme.

In the first two, standardization and systematization, the expense which would be created by carrying them to an extreme would act as a check against the continuance of such a condition, but that check would not exist in that portion of stimulation which is applied to the workman. The expenses of standardization and systematization are borne by the management, while the expense of stimulation in the form of increased energy is borne by the workman. Any system of shop change through standardization or systematization which is too heavy for the shop to bear or which imposes burden charges through stimulation which are too heavy for the workman to bear, should be discontinued.

Loafing and Labor Distinctions.

That there is loafing or soldiering among workmen has been shown by the testimony before your committee, but it is not general nor does it occur in numerous instances compared with the total number employed. Ordinary intelligent management under any system could eliminate it entirely, or, at least, reduce it to the point where it would not be a serious hindrance to production. Because there are some loafers is no reason why the remainder of the workmen should either be compelled or induced to work up to the very edge of the breaking strain.

There is need for production at the lowest cost, but no economic necessity can justify workmen being required to speed up to the highest point which they can continue from day to day and from year to year, even without injury to their health and strength. To place workmen in a position of that kind is to put them in the position of a beast of burden, which is required to go on from day to day performing a given task. There is a margin between the work performed by the loafer and the maximum task for a man. In that margin lies a proper day's work. What constitutes a reasonable day's work can only be determined by practical experience and intelligent observation. It can not be wholly determined by a stop watch or any other time-measuring in-

strument used only for a brief period of time.

Man Not a Machine.

By the stop watch you may be able to determine the time in which a piece of work can be done, but you do not thereby also determine the length of time in which it ought to be done. The time study of the operations of any machine can be made with a reasonable degree of accuracy, because all of the elements can be taken into consideration in making the computation. A machine is an inanimate thing—it has neither life, brain, sentiment, nor place in the social order. With a workman it is different. He is a living, moving, sentient, social being; he is entitled to all the rights, privileges, opportunities and respectful consideration given to other men. He would be less than a man if he did not resent the introduction of any system which deals with him in the same way as a beast of burden or an inanimate machine.

Time Study Unreliable.

In making a time study of the operations of a workman, all of the elements cannot be taken into consideration, and consequently, the computation cannot be made with mathematical accuracy. There is no work that can be performed, or that is performed, that is not preceded by a mental process on the part of the workman. The more skill needed in the work, the greater the mental process which precedes the expression of it.

So far as your committee has been able to learn, there is no method known to scientific management by which a time study can be made of the mental process preceding the physical act. The elements of the mental process not being susceptible of determination by a stop watch time study, the study of itself must consequently be inaccurate and the workmen are justified in objecting to such a time study being used as a basis upon which to compute their day's work and compensation, when in their judgment injustice is thereby done them.

Stimulation Methods Adopted.

In an effort to stimulate workmen to increased activity, various methods are used under different systems—such as discharge, fear of discharge, stop watch time studies, and bonuses. The fear of discharge exists under any system, and, no doubt, will continue to exist and to act as stimulus. The establishment of a premium or bonus presupposes the establishment of a task. The bonus system is based upon the establishment of a task large enough for an ordinary day's work and then giving additional compensation as an inducement to a workman to do more than he would ordinarily do.

Employer and Employe Co-operation.

The proponents of the Taylor system assert that the workman will be protected against any injustice either in the amount of work required of him or the compensation for that work by a change in the mental attitude brought about by the introduction of the system. A mental attitude which produces a spirit of co-operation between the employer and the employe is much to be desired, but such a spirit is not the result of any particular system of management, but is due almost entirely to the personality of the management and employe and the spirit that prevails in their relations to each other.

Your committee is of the opinion that the mere mental attitude of the employer is too variable and unsubstantial a basis upon which to rest the material welfare of the wage worker. Standardizing and systematizing of work can be introduced successfully without any change in mental attitude from that which exists in the ordinary shop, but when it comes to introducing stimulation, a change of mental attitude by which the workman is willing to give a greater amount of energy for the same amount of pay may be very desirable to the employer of labor, but it is not always so desirable to the employe.

Standardization Desirable.

The Taylor system undertakes to standardize the tools, machines, nuts, bolts, etc., so as to eliminate as far as possible the loss of time and waste energy resulting from the lack of standardization. This is "a consummation devoutly to be wished." It was shown to your committee that in the Watertown arsenal, prior to the change in system, there were several kinds of gear cutters run by one man. They were of different makes, capacities and ages, and operated on different principles. It was also shown that the nuts and bolts used were not standardized and consequently much time was lost by the workman in searching for sizes for his machine. This is not good practice.

The machinery should be standardized —made alike in principle, if not in size, so that the time of the workman need not be wasted over different kinds of tools in an effort to find the right one. It is an advantage to have standard hand tools in our shops, as far as possible. Similar operations on similar work can be advantageously done in a similar way. It is a great waste of effort and thought to perform one operation in one way to-day and in another way to-morrow. It is a still greater waste to perform one operation in three or four different ways at the same time.

Where there is no standard, a man never gets a chance to produce the best results, and even when he works hard he makes a comparatively poor showing. Standardizing can, however, be carried too far. When standardization has reached the point that the cost of maintaining it is greater than the saving resulting therefrom it should be discontinued.

Any system that eliminates unnecessary and wasted effort is good. It does not necessarily follow, however, that because any particular system has been branded as scientific that the brand alone makes it such. Conditions vary in different shops and a system which would be effective in one might not be as effective in another. The work and responsibility of selecting, evolving, or introducing a system suitable to a particular shop must in a great measure depend upon the intelligence of the management.

Management Intelligence.

The Taylor system undertakes to systematize the work, first, by the establishment of a planning department; second, by detail study of the shop and the elements of a particular piece of work; and third, by a routing system; out of all of which grow a multiude of other details, such as job cards, routing cards, time study, and many others. So much of this kind of detail work is needed under this system that it appears to your committee that constant care would have to be exercised in order to prevent the overhead charges thus created from using up all of the benefits which might be derived from the proper systematization of the work that is under way.

Every well-regulated industrial establishment should have a planning department proportioned to the size and need of the shop. In establishing a planning department, practical common sense should be used the same as in everything else. In a small shop, the manager might easily be his own planning department. In large establishments a separate department could be utilized to advantage for the proper planning of the work. In other words, every shop should be provided with the means of properly planning the handling of all work that comes to it so as to get it through the shop with the least possible waste of energy or loss of time to either men or machines.

A detailed study of the elements of every piece of work for the purpose of discovering the best system of handling it and the elimination of unnecessary work on the part of the workman may be, and no doubt is, under some circumstances, productive of good results. This is particularly true when unskilled men are selected to do skilled work and it becomes necessary to study their movements in order to train them to that

standard of efficiency which skilled men have already attained; but it is neither as essential nor as beneficial where men are employed, who are trained and skilled in the particular line of work they are expected to do.

Elimination of Unnecessary Motion.

The elimination of unnecessary motion in doing any work is always a benefit, because it conserves the vitality of the workman and makes his labor more productive. It should, therefore, be the duty of every foreman to observe the efforts of his workmen with a view of correcting any improper methods and removing unnecessary motion in their work. It cannot, however, be expected that every workman who has spent the greater part of his life in doing work by methods which have become familiar to him would in all instances become more efficient by the adoption of some other method, even though the other method eliminated unnecessary motion. In the judgment of your committee, the determination of whether or not a detailed study of the methods of the workmen should be made, would, in a great measure, depend upon the skill or lack of skill of those required to do the work.

Routing of Work.

It is always an advantage to have the work properly routed through the shop, although it is not at all time necessary that a routing card should be made out to accompany the work. In small shops the routing might be done very effectively by the oral direction of the foreman. In larger establishments, routing cards are beneficial for the effective handling of the work, and they are made more effective when the machines are properly arranged and grouped, so that the work can pass through with as little handling as possible, but even in large shops where the same work is being duplicated day after day it would be a waste of time and an unnecessary expenditure of energy to furnish a routing card for any job after the work has reached the point where it automatically routs itself. Here is the crux of the difficulty in the introduction of the Taylor or any other system of so-called scientific management. So far as the workmen are concerned, they have not made any serious objections before your committee to standardizing or systematizing of the work, but they have vigorously protested against stimulation on the grounds that it tends to injure their health through overwork, and that while their wages may be temporarily increased, the result is that they are ultimately required to expend the greater amount of energy without receiving any additional pay.

In the judgment of your committee the best and most effective stimulus that can be given to the work in a shop is to secure and hold a fine spirit of cooperation with the management on the part of the workmen. That cannot be secured through timing the operations of the workman with a stop watch when he considers such a procedure an indignity which recognizes him as being in the same class as a beast of burden or a machine, or when he considers such a time study inaccurate, and, therefore, unjust to him, or when he knows that it is to be used as a basis from which to compute the speed at which he must work and the wages he is to receive; when in his judgment the work, speed and wage rate are being established in order to secure greater profits for the employer at the expense of the workmen.

A straight piecework basis may be used as a stimulus to workmen without injury to them, on work that is continuously duplicated for a prolonged period of time, provided the workmen are so situated that they can protect themselves against the entire power of the management being centred upon them individually to compel them to work beyond their normal capacity, and provided, further, that they can secure a satisfactory guaranty that when the piece rate has been once established it will not be reduced unless the methods of production are materially changed, and reduced then only in proportion to the reduction in mental and physical energy required in the production of the article. In any form that stimulation may be used, except that of true cooperation, continuous care must be had that quality is not sacrificed to quantity.

READER, WHAT DO YOU KNOW?

Among readers of Canadian Machinery there is a clearly defined sincerity of desire to know how each overcomes the daily tasks of the machine, pattern and blacksmith shops, the foundry and boiler shops. It is believed that your methods and devices, while good, may be improved, and thereby made more valuable if you publish them, so that other brains may work on them. We will provide the setting and pay you for the material. When your fellow tradesman puts the superstructure on your foundation, we pay him and pass the "kink" on to you, free. Get into the game.

Conclusions and Recommendations.

Neither the Taylor system, the Emerson system, the Gantt system, the Brombacher system, the Stimpson system, nor any of the systems of so-called scientific management have been in existence long enough for your committee to determine with accuracy their effect on the health and pay of employes and their effect on wages and labor cost. The conclusions we have arrived at are all based upon what we consider to be the logical sequence of the conditions existing or proposed. The selection of any system of shop management for the various government works must be to a great extent a matter of administration, and your committee does not deem it advisable nor expedient to make any recommendations for legislation upon the subject at this time.

We recommend: Wherever possible, in Government work, that machines, tools, nuts and bolts should be standardized; the management using continuous care that the cost of standardization shall not exceed the benefits to be derived from the same. The management should at all times give studious attention to the proper systematizing and routing of work, the grouping of machines, the furnishing of proper tools and equipment, and the elimination of waste motion and waste energy on the part of the workmen. Careful study should be made of machines in order to attain the speed and feed which will secure the highest and best possible production.

The management should put forth every effort to invite and induce full cooperation between the working force and themselves, and should, therefore, deal with the working force in the most open, frank and candid way, affording the fullest opportunity for consultation and explanation in advance of proposed action affecting the interests of the workmen.

Stop watch time study should not be made of workmen without their consent or any conditions imposed upon them by authority which imply any indignity. Piecework may be introduced where the work to be performed is a continuous duplication, but with the express understanding that piecework rates shall not be cut unless the conditions of production are materially changed. In other cases, the rate should be a straight daywage rate at the highest prevailing rate for a similar class of work in the neighborhood where the Government work is to be performed, except that by mutual consent, bonus and premium work may be introduced, but only with scrupulous care that the workman shall have full opportunity for increasing his earnings without risk or overstrain, for collective bargaining if he should so desire, and for easy and direct appeal to the management in any cases where he may think his interests threatened.

Personnel of the Committee.

The personnel of the committee of investigation was as follows: W. B. Wilson, chairman, Pennsylvania; William C. Redfield, New York; John Q. Tilson, Connecticut. Mr. Redfield is vice-president of the American Blower Co., Detroit, Mich.

C.N.R. MACHINE TOOL REQUIREMENTS.

THE Canadian Northern Ry. has issued from Winnipeg a list covering its 1912 requirements of machine tools, for which tenders will be considered in the near future. The list is as follows:—One 80-in. drive wheel lathe, complete with 220-volt direct current motor and controller: one 42-in. double head upright boring mill for boring tires; one hollow spindle turret lathe, capable of taking bars up to 6 ins. diameter; one 24-in. upright shaper; one 14-inch upright slotting machine; one hollow spindle turret lathe, capable of taking bars up to 2⅛ ins. diameter; one 18-in. brass turret lathe; one 20-in. brass turret lathe; one 20-in. sensitive drill press; one 36-in. back geared drill press; one 8-in. pipe threading and cutting machine; one 2-in. double head bolt cutter; one 1½ in. triple head bolt cutter; one 48-in. blast fan for supplying air to oil furnace; one motor driven air compressor, capacity 1,000 cu. ft. free air per minute, compressed to 115 lbs.; one Lassiter automatic stay bolt drilling machine; one roller type tube welding machine; one 1-in. 6 spindle, semi-automatic nut tapping machine; one 24-in. planer; one 8-roll patent triple cylinder sandpapering machine; one scroll sawing machine; one 4-spindle Universal boring machine; one Universal dado and saw machine; one rod, dowel and pin machine; one band-saw with 36-in. wheels; one concentric slide wood turning lathe; one 2½-in. double bitted surface planer; one 6-spindle vertical stay bolt threader; one No. 8 Beaudry Champion power hammer; one No. 3 washer cutting machine; one 36-in. Bullard vertical turret lathe; one 24-in. by 36-in. by 14-ft. gas engine lathe; two 24-in. column shapers; two 36-in. back geared upright drill presses. The approximate cost of the whole will be about $35,000.

MANITOBA BRIDGE & IRONWORKS CO.

NORTH Transcona is to have another big manufacturing plant before the close of the year. It is learned that the Manitoba Bridge and Iron Works Limited, have secured an option on 30 acres in the southwest quarter of 16: 11:4 east, as a site for a million dollar steel plant. The property in question lies east of the new C. P. R. yards at North Transcona and is at the junction of the lines of the Canadian Northern and Grand Trunk Pacific railways. The price named is $1,000 an acre.

T. R. Deacon, president and general manager of the Manitoba Bridge and Iron Works, Ltd., recently returned from Gary, Indiana, where he has been inspecting the plant of the American Bridge Company. He was accompanied on this trip by H. A. McKay, chief engineer of the Winnipeg concern. The plant of the American Bridge Company is said to be the most modern of its kind on the American continent, and the new plant at Transcona will be modelled upon similar lines to that now in operation at Gary. Engineers of the Manitoba Bridge and Iron Works are preparing plans and it is expected that construction will commence shortly. The first building to be erected will be a bridge building plant, 160 feet by 90 feet, and other buildings will be added as rapidly as possible.

The president of the company states that the new plant will be in operation by January 1, 1913.

CANADA'S TRADE.

CANADA'S total trade for the past fiscal year amounted to $862,699,732, an increase of no less than $103,605,343, as compared with the preceding fiscal year. Imports totalled 547,382,582, an increase of nearly $86,000,000; exports totalled $315,317,250, an increase of nearly $18,000,000. The year's increase in trade—over 14 per cent., is one of the largest, if not the largest, in the history of Canada. According to present indications, the Dominion's trade for the current fiscal year will run very close to the billion-dollar mark.

Imports and Exports.

Of the total imports for the past year $335,204,452 were dutiable goods, while 186,144,249 were free goods. The Customs revenue totalled $87,548,252, an increase of $14,250,908.

Exports of domestic products for the year totalled $290,223,857; the principal items being:—Agricultural products, $107,143,375; animals and their produce, $48,210,654; mines, $41,324,516; forests, $40,892,674; manufactures, $35,836,284; fisheries, $16,704,678.

The increase in agricultural exports was approximately $24,500,000. In manufactures the increase was not quite half a million. Fisheries exports increased by a little over a million. On the other hand, there were decreases of a little over four millions in the exports of animals and their produce; nearly five millions in the exports of the forest, and a million and a half in mineral exports.

During the year Canada imported coin and bullion to the value of $26,033,881, as compared with only $10,206,210 for the preceding year.

ECONOMY OF LIFTING MAGNETS.

THE economy resulting from the use of lifting magnets in large engineering and machine shops is illustrated, says the "Engineer," London, by the following details:—In one important ironworks, wagons were formerly unloaded by hand, and a 50-ton truck kept a gang of five men busy for four hours. After the introduction of lifting magnets, the unloading was accomplished in one and a half-hours. In large works, such a saving in the course of a year amounts to a considerable sum.

The portion of the magnet most liable to wear and tear is the pole shoe, which comes into direct contact with the material lifted, but as this is secured by bolts passing through the body, it can be easily removed when worn and a new part fitted. It is important to note that experience has shown the advantage of through bolts over cap screws or studs, which are liable to rust in and can then be removed only with difficulty. In addition to the works already mentioned, these lifting magnets are useful in foundries, blast furnaces, and rolling mills for lifting and transporting metal too hot to be handled. Castings can be readily handled which on account of their shape or unequal distribution of weight would require careful adjustment of hoisting tackle. Armor-plate and thin sheets of iron or steel used in the manufacture of pressed steel or iron car wheels and many similar finished articles, as well as raw products of foundries and machine shops can be readily and cheaply dealt with by electro-magnatic lifters.

THE WARREN AXE & TOOL CO.

The Warren Axe & Tool Co., Warren, Pa., has voted an increase of its capital stock to $200,000 to take care of its growing business in axes and logging tools. It contemplates the erection this year of a factory at St. Catharines, Ont., for the manufacture of these products. The Canadian company will be known as the Canadian Warren Axe & Tool Co., Ltd., and will have a paid up capital of $150,000. The officers of the American company are: President, E.E. Allen; general manager and treasurer, H. P. Stone; secretary, W. A. Kinnear; superintendent, D. W. Murphy.

Vol. VIII. JUNE, 1912 No. 6

WHAT DO YOU KNOW?

WHAT do you know? is a salutation expressive of a desire for suggestions and information from the work and experience of the party addressed, whereby the questioner may possibly enhance an already well developed intelligence and apply the information obtained to his personal profit and general usefulness. The same salutation would in many cases be an opening for the introduction of the latest gossip on the part of men as well as women, and would naturally have the reverse effect as regards acquirement and development of intelligence.

"What do you know" seems to us to imply the exercise of eye, ear and hand, each directed and governed by an active and reasoning brain system. Sub-dividing, we might call the exercise of ear and eye a well developed habit of observation, and that of the hand the instrument for putting it into effect. Illustrative of the point and something familiar to all of us, as a not altogether remote possibility, is a crowded street car going along at a good clip with the motorman just fallen in a faint. "What do you know" about controlling a street car, might be a very painful experience for you if a woman elbowed your fear-shaken frame to the one side and took charge.

A myriad other awkward situations might be cited as necessitous of silent observation and mental record, the majority of which may become apparent to the reader on a little reflection. Emergencies arise every day for the exercise of somebody's observation—"what somebody knows," and the trained man or expert may not happen to be there. As a matter of fact the irony of fate seems to rule it otherwise and the novice or amateur is called upon to avert or mimimize disaster and preserve life.

It is incumbent we think on the part of everyone, to cultivate a keen observation and perception of the conditions by and under which we live, not only with respect to our own particular and chosen calling, which, of course, must always have precedence, but in the various accessory features as well, that go to make a day's life and work. The man who observes most and knows most in his own particular line is the more likely to keep his eyes and ears open and alert for pointers in other fields, and while this latter is here perhaps given extra prominence, its inception and operation like charity must begin at home.

Interfering with the rights, privileges or professions of others is in no sense meant to be conveyed in the foregoing, because that particular species of "what do you know" needs no cultivation, being naturally innate, of luxurious growth and hurtful. What has been commended, is and will be helpful to ourselves and others when an emergency arises, and while we may not be as graceful and apt as the trained man, the result can be the same, thanks to "what we know" from cultivation of the faculty of industrious observation.

WELL-SELECTED IGNORANCE.

THE call for well selected ignorance is a universally personal message to all classes and conditions of men. It takes for granted that from choice, indifference or circumstance, a degree of ignorance exists and is cultivated.

We are daily acquiring knowledge of some sort (being educated if you like) without much effort in its pursuit. Idle curiosity leads to its attainment, but it is knowledge of no moral and commercial value. A superficial smattering of the principles underlying one's business or occupation is also an acquisition of knowledge. Contentment with it, however, displays choice and cultivation of ill-selected ignorance; the antithesis of our subject.

We do not purpose here to treat the matter in its wider application, but rather to bring before our readers the fact that they have many superfluous frills in their trade get-up which a better-selected ignorance would tend to remove. Experience goes to show that men have an antipathy to let their equals know the extent of their knowledge, or put in another way and with the same meaning, the extent of their ignorance. Further, when opportunity offers by which valuable information is to be had for the asking, there is paraded that display of self pride whose inevitable result is, of course, ill-selected ignorance.

The picture drawn is no fanciful one and every reader can take it home to himself and say "that's me." We are all built that way, unfortunately, but need not as a consequence remain altogether and all the time under the thraldom. Get a beginning made, now, to help shake it off, by cultivating a well selected ignorance which is equivalent to the acquisition of a thorough detail education, involving the principles, the "whys and wherefores" of your business, and the grasp of every opportunity to add to it. It will save you many a hard knock, harder I assure you than the wounding of your pride by choice, to an inferior or equal. It will make a man of you as well as an expert operator, and if you cannot command success, you will at least deserve it.

MACHINE SHOP METHODS AND DEVICES

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

Spur Gear Features

By G. D. Mills.

AN automatic gear cutter will cut tooth spaces on the circumference of a wheel with great accuracy, but rotary cuttters which have a range of two or more teeth, can only be perfect for the lowest number of teeth in the range. Thence it follows that in order to preserve the precision in spacing, and also the profile, a correct templet must be provided to finish the teeth, if a perfect wheel is desired. Unequal spaces between the teeth cannot be detected by looking at a wheel, nor can they be detected by calipering the width of the teeth. They can, however, be detected when the wheel becomes noisy and transmits a jerky motion. This is a sure indication that too much metal has been filed from some of the tooth faces; and while it is true that a pair of wheels will rattle a little when they are nearly worn out, this tendency cannot exist after a short service unless they were defective when first set up. A pair of true wheels will run smoothly and wear uniformly.

Spokes.

Respecting the proportions of the spokes in a wheel, the thickness of spoke should be 4-10 of the width and the taper ⅜ inch per foot per side. It is desirable to have full webs in wheels of 30 teeth and less, and a simple rule to determine the width of spoke in normal gears may be stated as:

$$\text{Width of spoke} = \frac{7}{P},$$

in which P equals diametral pitch. We are indebted to Mr. E. H. Wood for this formula, being an empiric formula of his calculations with respect to new gear spokes in Sibley Engineering, 1907, and while it serves as a most excellent guide in normal wheels, it should not be considered an absolute rule. If desirable to calculate spoke proportions, they may be considered as cantilevers loaded on the ends, and the load equally distributed on all the spokes.

In the example given, the wheels are required to transmit a load of 1050 lbs., and the cast iron gear has a pitch diameter of 9 inches. If we decided to use three spokes in this wheel, the length of each spoke would be about 3 inches, and the load on each spoke equals

$$\frac{1050}{3} = 350 \text{ lbs.}$$

We therefore have a cantilever 3 inches long, loaded on the end with 350 lbs., and the bending moment of this cantilever, therefore, equals 350 lbs. × 3 inches = 1050 inch pounds. The ultimate tensile strength of cast iron may be taken at 18,000 lbs. per square inch of section, and if we decide to use a safety factor of 6, the safe tensile strength of the material is 3,000 lbs. per square inch of section. The section modulus, therefore, equals

$$\frac{1050}{3000} = .35.$$

The width of spoke obtained by Mr. Woods' formula

$$= \frac{7}{P} = \frac{7}{4} = 1\tfrac{3}{4} \text{ inches,}$$

and its thickness

$$= 1\tfrac{3}{4} \times \frac{4}{10} = .7.$$

The section is, therefore, 1¾ × .7, and the section modulus of a rectangular section in which the neutral axis is perpendicular to the longest side

$$= \frac{b \times d^2}{6} = \frac{.7 \times 1\tfrac{3}{4}}{6} = .3572,$$

in which b = short side and d = long side of rectangle. The section modulus obtained, therefore, agrees very closely with that obtained by considering the spoke a cantilever loaded on the end.

When the wheel is abnormally large, it may be necessary to depart from the rule, width of spoke $= \frac{7}{P}$, which serves as a guide in normal wheels, and determine the section modulus from the allowable unit stress in lbs. per square inch of material and the bending moment, as above, only. In this case, the dimensions of the rectangle would have to be found from the section modulus by means of the ratio of the width to the thickness of spoke, as embodied in the formula

$$d = \sqrt[3]{\frac{K \times 6}{\frac{b}{d}}},$$

in which K equals section modulus, and

$$b = d \times \frac{b}{d}$$

SPOKE FORMULAE.

Width of spoke $= \frac{7}{P}$

Thickness of spoke $= \frac{4}{10}$ width

Load on each spoke $= \frac{\text{total load}}{\text{number of spokes}}$

P = Diametral Pitch

M = Bending Moment $= K \times S$

S = Allowable Unit Stress of material in lbs per square inch $= \frac{M}{K}$

K = Section Modulus $= \frac{M}{S} = \frac{b \cdot d^2}{6}$

b = short side of rectangle $= \frac{K.6}{d^2} = d \times r$

d = long " " " $= \sqrt{\frac{K.6}{b}} = \sqrt[3]{\frac{K.6}{r}}$

r = ratio of sides $= \frac{b}{d}$

Spur Gear Features.

The formulae are original, insomuch as they are the outcome of the necessary calculations imposed by the conditions of this article.

If we desired to preserve the ratio of thickness $= \frac{4}{10}$ of width, the formulae reads:

$$d = \sqrt[3]{\frac{K \times 6}{.4}}, \text{ and } b = d \times .4.$$

The formulae serve a most useful purpose in this case, and are equally so for similar conditions. I have devised a companion formula in which the neutral axis is perpendicular to the short side, which will be published later in book form. The formulae devised for spokes may be stated as follows:

The ultimate tensile strength of cast iron as above is 18,000 lbs., and a safety factor of from 6 to 10 should be used. In the above comparison, a safety factor of 6 was used, but in large wheels it would perhaps be safer to adopt 10 instead of 6. The ultimate tensile strength of steel is 60,000 to 65,000 lbs. per square inch, with which a safety factor of 3 or 4 should be used. The safe tensile strength of cast iron is, therefore, 1,800 to 3,000 lbs. per square inch, and that of steel 15,000 to 20,000 lbs. per square inch.

Results From Comparison of Values.

In comparing the values obtained by the Lewis formula for the strength of gear teeth with the shearing value of the metal in one tooth, I have obtained the following with respect to the pair of wheels in the example given in this article. For the pinion, the compressive strength of steel and high test iron may be assumed as 13-15 of its tensile strength, and its shearing strength at 5-6 of its compressive strength. If we take the safe tensile strength of steel at 10,000 lbs. per square inch, using a safety factor of 6 for varying stress, its compressive strength = 13-15 of this, or 7,666 lbs., and its shearing strength 5-6 of 7,666 lbs., or 6,385 lbs.

The average shearing area of the tooth may be assumed as the chordal width × face length = .3915 × 2 = .783 square inch, and the shearing strength of the metal in one tooth = 6,385 lbs × .783 square inch = 5,000 lbs., which is well over that obtained by the Lewis Formula of 2,419 lbs. For the cast iron gear, the shearing strength of cast iron is equal to its tensile strength. A safety factor of at least 10 should be used for varying stress. The ultimate tensile strength of cast iron being 18,000 lbs. per square inch, its safe tensile strength is 1,800 lbs. per square inch, and its safe shearing strength is the same. The shearing area of tooth as before = .3924 × 2 = .7848 square inch. The caliper width for the gear being .3924 inch, and for the pinion .3915 inch, the shearing value of the metal in one tooth of the gear, therefore, = 1800 lbs. × .7848 sq. in. = 1412 lbs., which is nearly the same result as obtained by the Lewis Formula, in which a value of 8,000 lbs. was used for cast iron. In view of the fact that this value steadily decreases as the speed increases, we may, therefore, assume that the Lewis Formula is all right, since we have compared the shearing value of the metal in one tooth without regarding the speed of the wheels, and have obtained nearly the same result for cast iron as the Lewis Formula, with its highest factor and lowest speed.

The angle of pressure on all involute gear teeth is always more or less oblique, depending on the angle of obliquity of the teeth. The load transmitted on the teeth when interchanging is always applied on the line of pressure, and is never applied at right angles to the tooth; while in cycloidal or double curve teeth, the pressure angle determined as for involute teeth, changes constantly when the teeth are interchanging; the load being transmitted on the teeth in a variety of directions. The pressure angle, therefore, determined for involute teeth, is all that the term implies, and for cycloidal teeth it is not. Involute teeth transmit unvaryingly angular velocity and cycloidal teeth do not.

From the preceding it will be seen that the selection of the chordal width of involute teeth to determine the average shearing area is a liberal one, as any one tooth cannot receive the full load only at or near to the pitch circle, and in an oblique direction. Again the point of a tooth will never be subjected to the strain of the entire load, unless the tooth spaces are unequal; because when the point of one tooth begins to engage the flank of its mating tooth, the preceding tooth is receiving the full load obliquely at or near to the pitch circle, if the wheels are true. While the tooth is not subjected to a direct shear, which may be taken to mean a piece of metal held firmly and subjected to a load which has a tendency to shear or cut, it is subjected to a similar oblique strain; therefore, the Lewis formula provides a strength equivalent to the average shearing value of the metal in one tooth, without regard to the speed.

A BABBITTING FIXTURE.

By D. O. Barrett.

THE bearing shown in Fig. 1 is for the crank end of the connecting rod of

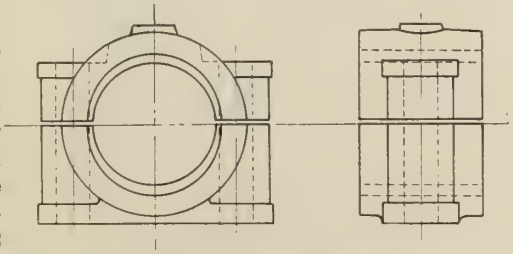

Fig. 1.—Babbitting Fixture.

a gas engine, and is a brass casting with a babitt liner cast in, the outer half being slightly less than complete to allow for adjusting shims. The fixture, Fig. 2, is provided with a half round arbor dowelled to the base casting and the brass is located by means of the pins fitting into the bolt holes,

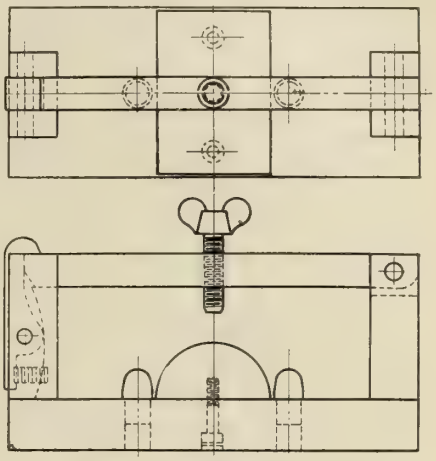

Fig. 2.—Babbitting Fixture.

which are first drilled. The bar at the top is pivoted at the one end and held by the spring latch at the other, while the screw at the centre ensures the brasses being properly pressed down.

Wooden pieces cut to the half round are held at the outside of the brasses with a patternmaker's clamp; one of these being provided with a vent, and the other with the pouring gates. When the outer half is poured, strips of wood the same thickness as the shims desired are slipped over the pins.

MAKING THREAD CHASERS.

By A. Leonard Marshall.

HAVING a large number of brass studs ¾ by 4 inches to make on an engine lathe I used the chaser shown in

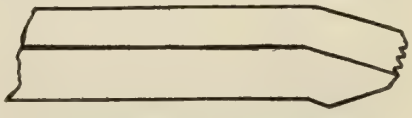

Fig. 1.—Making Thread Chasers.

fig. 1, and found that by so doing I could make the tool and thread the studs in one third of the time allowed for the job.

To make the chaser, I centred a ¾ tap in the lathe, and used it as a hob. After

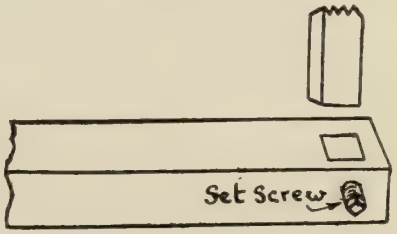

Fig. 2.—Making Thread Chasers.

getting a piece of tool steel annealed and offset as shown, I secured it in the tool post and geared the lathe for 10

threads per inch. I then fed the tool against the hob, while the carriage was advancing, until I got a full thread. I next raised the tool a little and repeated the operation to give the tool clearance. The next step was to chamfer the first few threads and temper. Three cuts only were required to cut a full thread in brass.

Large pipe flanges are now being successfully threaded in our shop by using the tool shown in fig. 2. The chaser is made of high speed steel and is secured in the tool holder by a set screw.

REPAIRING A CHATTERING PULLEY.

By J. H. R.

THE sketch herewith shows the method adopted some time ago in repairing a loose pulley, which would persist in chattering when running, either with or without the belt.

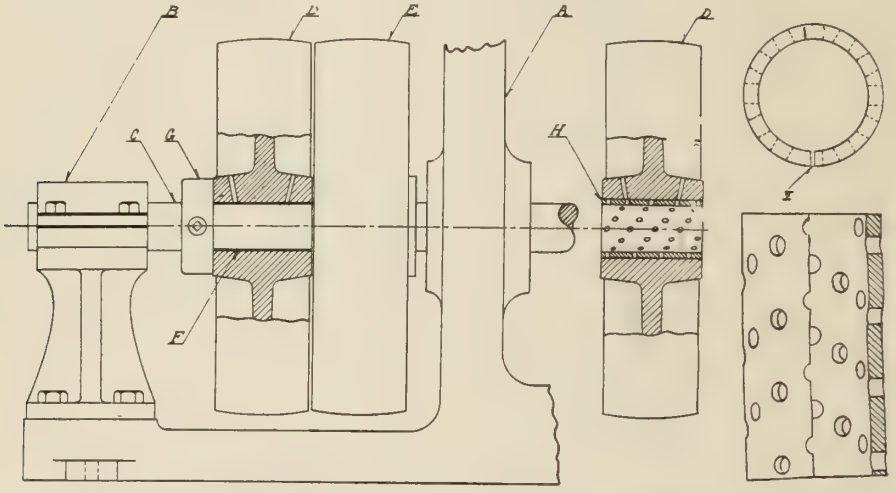

Fig. 1. Fig. 2. Fig. 3.

Repairing a Chattering Pulley.

The shaft (C) was in such a position that it was not very convenient to remove it from the machine, and as the part (F) was worn nearly a 1-32-inch below original size, although comparatively round, it seemed a difficult matter to remove the play between the shaft and the pulley. This latter amounted to considerably over 1-16 of an inch; the pulley being worn slightly more than the shaft.

Detail of Repair.

The housing (B) was removed, the loose pulley taken off and bored out to receive the bush, fig. 3. The bore of the bush was made a shade loose for the worn part of the shaft (F), and a sliding fit in the loose pulley. The bush was then slotted the entire length, as shown in fig. 3; numerous holes being drilled about the circumference and filled with lubricating grease. It was afterwards sprung over the large part of the shaft to its position at (F), the shaft being about 2¾ inches diameter, and the bush about ¼-inch thick. A brass liner was placed in the slot (I) and the pulley slid over the bush.

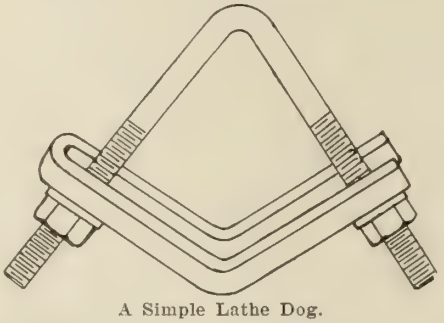
With the putting-on of the belt the result was highly satisfactory.

A SIMPLE LATHE DOG.

By T. R.

THE lathe dogs listed by manufacturers of such goods are made in certain definite sizes; consequently the machine shop must be equipped with all sizes and with more than one of each size if many lathe hands are employed. Sometimes when a job is to be turned, you may find that you have not a dog that will fit the part to be driven, and in such a case the device here shown will prove most useful, as it may be quickly and cheaply made up to suit any size of work.

Take a piece of 1½ inch iron or steel, 16 inches long, and bend it into the shape of the letter (U); the width between the legs being slightly more than ½ inch. Then, at a point half way up the (U) bend the two legs forward through angles of 90 degrees. Next, take a piece of ½-inch rod, 16 inches long, thread it for 4 inches at each end, and bend it through an angle of 90 degrees from its middle point. All that now remains to do is to assemble the device with two nuts and washers, as shown in the cut.



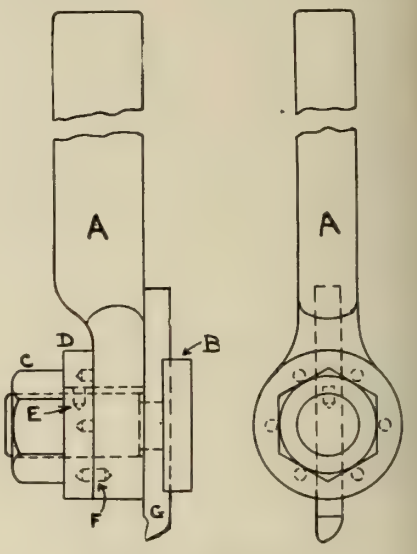
A Simple Lathe Dog.

HANDY PLANER TOOL.

By W. A. P.

THE accompanying illustration shows a tool that has proved very handy for planer use.

A is the stock; B the clamping bolt and C the nut. The dowel pin E is driven tight in the bolt B, and fits in a keyway cut in the washer D, and also in the stock A. Another dowel pin F is driven into the stock A, and the washer D is drilled with a number of holes to fit same as may be seen in the front view. By means of these holes the cutter G can be positively set at many different angles. The cutter passes through a square hole cut in the body of the bolt B, as shown.



A Handy Planer Tool.

LOOSE PULLEYS.

By Donald A. Hampson.

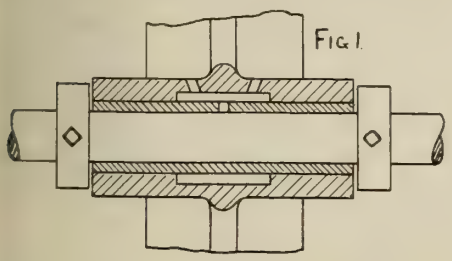
THE loose pulley problem is not a new one, but like the poor, is always with us. In the machine shop, the question is not so serious as in the wood-working shop, but it nevertheless demands attention.

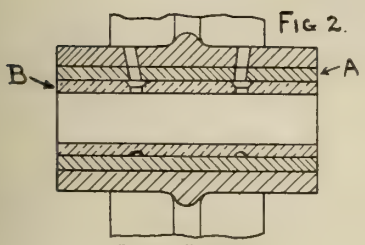
Automobile builders in their instruction books are unanimous in affirming that the greatest repairer is the oil can. The same remark might be applied to the loose pulley, with the corollary that "given an oil can, a free passage-way for the oil must be provided." On account of a blockade of dirt, too much of the oil poured into an oil hole often backs out, and perhaps falls on the head of some innocent victim below. Another difficulty which the oil-can has to overcome is caused by the lack of recesses or grooves at the bottom of the hole. One squirt of the can emits a 20-drop stream that is directed at a 5-drop hole, whereas a drop in the right spot is worth a flood in the wrong.

In the writer's opinion, one of the most serviceable types of construction,

having regard to relative low first cost and cheap renewal possibilities, is shown in Fig. 1. The hub of the pulley is bored and bushed with a thin cast iron liner, reamed very smooth and having on its inside a shallow spiral groove, making about one turn to the inch. This groove is fed by an oil hole which leads out of a rough bored recess in the hu of the pulley. Provided that the oil holes to the outside are kept in a passable state, conditions are very favorable to a long life for this arrangement, since there is a sufficient reservoir with a small outlet; the latter feeding oil through the spiral groove to the ends of the hub, lubricating the shaft as it passes, and driving out air before it. Collars should be set as shown, in order to give the pulley a little end play on the shaft. A total side movement of ¼ inch will be sufficient and a gratifying freedom from early trouble may be expected.

While doing some work in a woodworking plant, the writer came across, what was to him, a new design of loose pulley. This is shown in Fig. 2 and it will be seen that the pulley has two bushings; one, (B) of bronze next to the shaft and one, (A), between the bronze bush and the hub. Bushing (A) is of cast iron and is pressed into the the hub. Bushing (B) is a running fit on the shaft and in the cast iron bush-





Loose Pulleys.

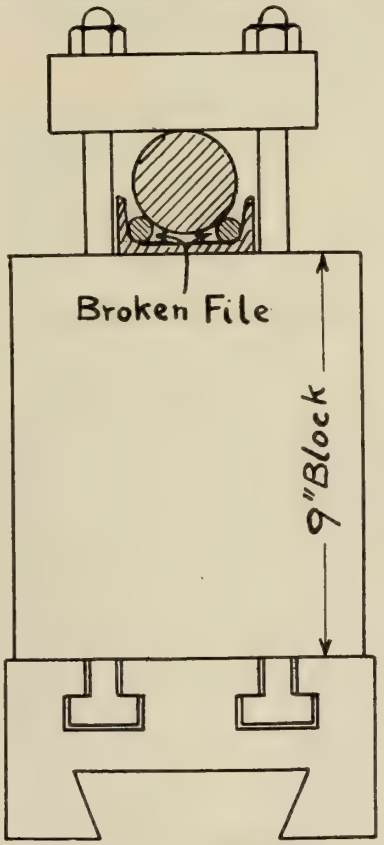
ing. On the outer surface of (B) are turned two grooves, each of which has several oil holes leading to the shaft. Oil holes through the hub and bushing (A) meet these grooves.

This design of pulley was in use on several machines in that particular shop and was giving splendid service under more than usually severe conditions. In theory the various units turned as a whole, until possibly things at the centre got warmed up to an unusual degree, when the inner bushing commenced to turn within the outer, and continuing to run thus, gave the shaft a chance to cool off, after which it resumed its normal function.

BORING A HARD CASTING.

By J. C. M.

I RECENTLY had a very hard casting to bore out in the lathe and was unable to use an ordinary boring bar



Boring a Hard Casting.

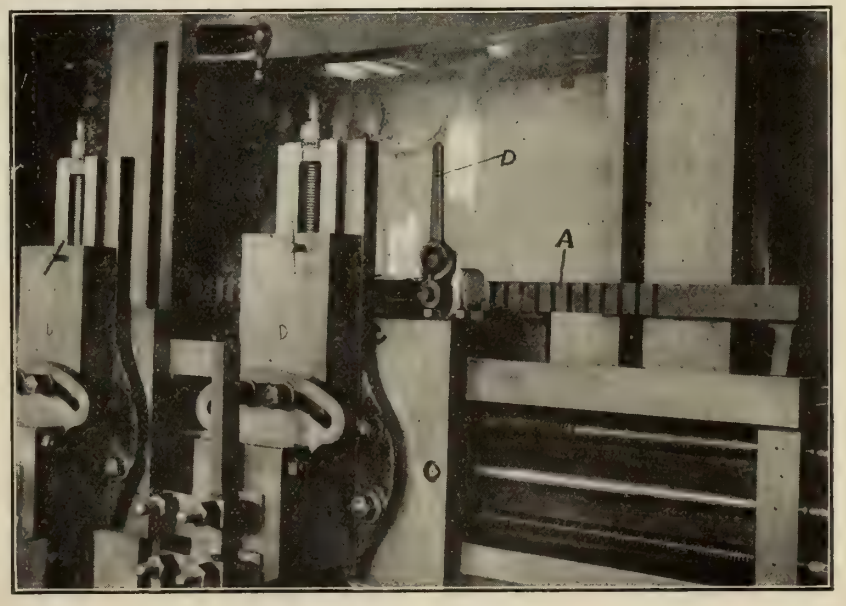
clamped in the tool post on account of a projection on the casting, which necessitated the lathe centres being raised 9 inches in order to swing the job. I raised the height of the slide rest a corresponding amount by placing a 9-inch block on top and clamped the boring bar to this with vee blocks. However, the casting was so hard that I found it impossible to prevent the bar from turning in the vee blocks, so I had to look around for some other means of holding it. Having read how a piece of round file makes an ordinary monkey wrench into an efficient pipe wrench, it occurred to me to use the same scheme for securing the boring bar. The illustration shows how it was done. I cut off two pieces of 3-inch channel iron, each 4 inches long, and placed them across the block. I then got two broken round files and put them in the corners of the channel as shown. All that then remained to do was to put the bar in place on top of the files, making sure that the bottom cleared the channel iron when clamped. This device proved entirely successful.

A RACK PLANING ATTACHMENT.

By Avery E. Granville.

THE attachment shown has proved very efficient for use in spacing the planer tool, while planing steel racks of a certain pitch. Two brackets hold the spacing bar (A) fast to the planer cross-rail, and a bracket (B) bolted to the cross-slide, carries an indexing pin (C), which is worked by the cam lever (D) and a spring inside of the bracket. In the position shown, the pin is out of the way of the notches in the bar, and the cross-slide may be moved as desired; but if the lever (D) is pulled to the right, the cam drops away from the small pin (E), and the indexing pin is left free to spring into the next notch that it passes.

This method is far more accurate than trying to space by turning the cross-feed screw a certain number of times,



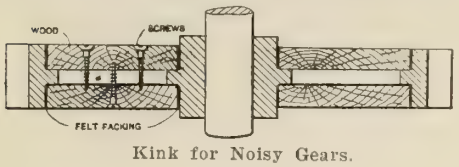
A Rack Planing Attachment.

and the time taken bears no comparison. Of course, in using this attachment we do not plane just one rack at a time, but, as a rule, place about twenty on the planer table at once.

KINK FOR NOISY GEARS.

From Practical Engineer, London.

THE gearing of a crane was placed in such a position that the noise resulting from its operation became highly



Kink for Noisy Gears.

objectionable. Several schemes were adopted to eliminate it. Grease and oils of all kinds were used, with but temporary success. Finally the following method was tried:—The annular space between the hub and the rim was packed with wood, which butted tightly up against felt pads as shown in the illustration. The pieces were secured to each other by ordinary wood screws, care being taken not to have the heads project. This method eliminated the objectionable noise.

It might be added that good hardwood should be used, also rubber, to advantage instead of felt, unless for exposed outdoor work.

QUICK REPLACE JOB.

By H. A. Wilson.

LATE on Friday evening a telegram arrived at Picton, Ont., from Windsor Mills, N.S., ordering a pinion to replace one which we had supplied some years ago. This pinion had a twelve-inch face and mated a bevel mortise gear. As our original pinion and gear patterns were designed for a face of eight inches only, we had extended temporarily the face, arms, hub, etc., to meet the above requirements. The pattern had been dismantled, however, to fill a simultaneous rush order for a gear in its original condition, namely eight inches face.

I came down early on Saturday morning and had the men clear the foundry floor, as we had run-off a cast the last thing on Friday night. The eight inches face pinion was molded in the morning and the cores made for both gear orders. At noon, the pattern was in the pattern room again, and at one o'clock, the patternmaker started to put on the additional pieces to make the pinion 12 inches face. He was finished at 1.45 p.m. The pattern was again in the foundry a few moments later, and by six o'clock the same evening, the gears were cast.

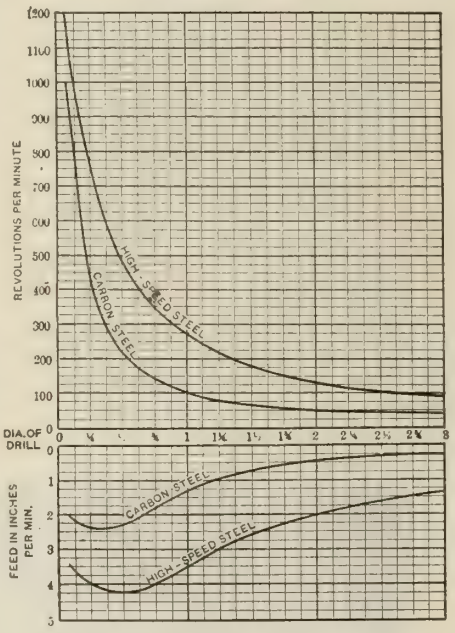
The Lord's Day Alliance prevents Sunday labor, so at 4 a.m. Monday, the gear was hanging in the crane being cleaned and chipped. We could not work at it on Saturday evening because the casting was too warm. By 6.30 a.m. Monday, it was in the lathe, being bored 4 5-16 inch. diameter, and having the hub faced on both ends, rim turned and keyseated. The teeth were then cut, and the gear shipped on Tuesday night.

The dimensions were:—

Circular pitch ....2.9 inches.
Face ....12 inches.
Bore ... . 4 5-16 inches
Keyway .... ½ by 1 inch
Weight ....714 pounds.

CUTTING SPEEDS AND FEEDS FOR TWIST DRILLS.

THE accompanying diagram devised by E. G. Wrigley & Co., Birmingham, England, gives speeds and feeds applicable to ordinary practice for high speed carbon-steel twist drills, when drilling mild steel. As the values given are not experimental or test rates, but

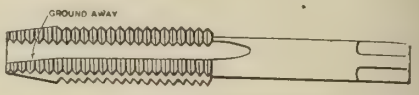


Cutting Speeds and Feeds for Twist Drills.

intended for everyday practice, they may, of course, be exceeded under favorable conditions. It is, however, generally desirable to keep the cutting speed comparatively low, so as to avoid overheating of the drill point, and consequent waste of power.

COLORING FOR PIPES.

THE uniform system of distinctive coloring for pipes in industrial plants, proposed some months ago in Germany, is being received with favor. It includes green for water, yellow for gas, blue for air, white for steam, black for tar, rose for lye, brown for oil, grey for vacuum, rose with red streaks for acids. A fuller indication of the contents of the pipes, pressure, temperature, impurities or admixtures is effected by a combination of the basic colors with stripes of red for danger, black for impurity, white for presence of steam, green for presence of water. The



Tap for Hard Metal.

direction of flow is indicated, if necessary, by arrows.

The same colors may be used in drawings, steam being indicated by fine double lines. The colors on the pipes are indicated by securely attaching to the pipes small painted and enamelled or varnished strips of iron 3 to 4½ in. wide.—Ex.

TAPPING HARD METAL.

From Practical Engineer, London.

WHEN hard metal has to be tapped, it is very common for the tap to break. If the tap is ground, however, as indicated in the engraving, no difficulty will be experienced. The effect of the grinding removes the front part of the teeth, so that the cutting edge presented forms a different angle with the thread than on the section not ground away. This method of grinding the tap proved successful in tapping very hard rolled steel plates.

Beginning with its June issue, The Merry Molder, published by the Osborne Mfg. Co., Cleveland, will award each month a prize of $10 in cash for the best paper on foundry practice written for that publication. The contest is open to all shop readers of the Merry Molder, including superintendents, foremen, moulders and laborers. The paper must discuss some example of improved foundry practice in which the improvement has been accomplished by an Osborne machine or accessory.

The method of producing fine brass castings in the leading brass centres of the United States, is to face the mold with Windsor Locks sand, then skin dry the mold and finally smoke the face with a gasoline torch. Except for undercut work it is not customary to dry the mold clear through, or to use French molding sand. The latter is employed for molding statues and similar work requiring false cores.

DEVELOPMENTS IN MACHINERY

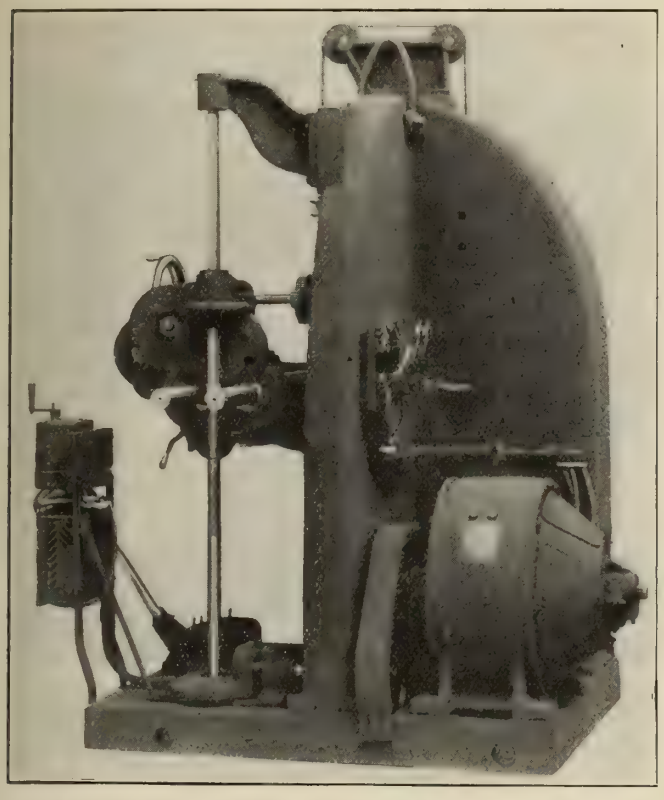
A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

SPECIAL REAMERS FOR LOCK GATE CONSTRUCTION, PANAMA CANAL.

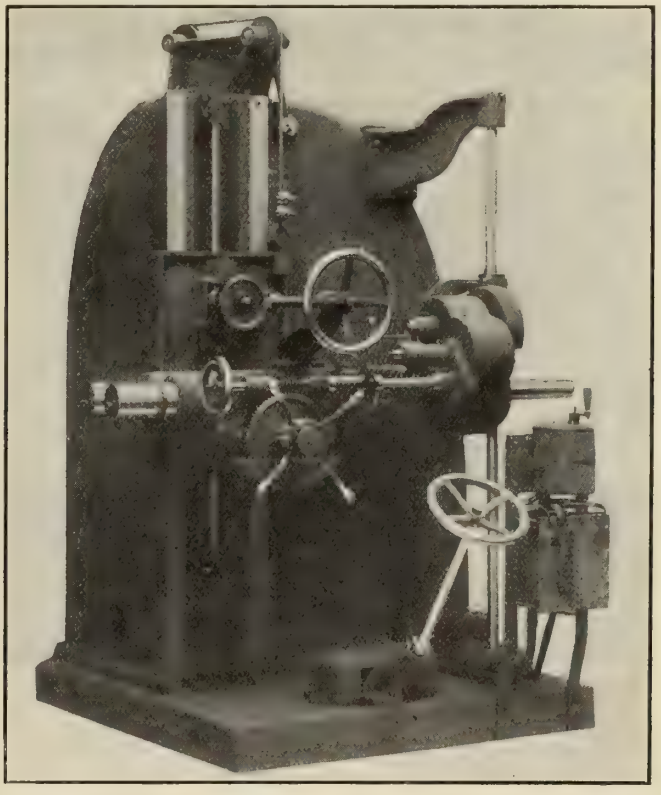
FOR the final riveting of lock gates, the skeletons and sheathing of which have been put in place at Gatun, the McClintic-Marshall Construction Co. has installed 8 special electric reaming machines. Each machine, which weighs 6 tons, carries two spindles, mounted on a heavy cast base and driven by a 10-horse power induction motor. That the machine may be carried over the face of the gate, it is mounted on a broad, adjustable scaffold, extending the length of the gate, supported by chain-blocks from brackets affixed to the gate top. Some of the holes on the upstream face of a gate are enlarged to a diameter of 1 1-16 inches, and others to 15-16 of an inch, and those on the downstream face are made 15-16 of an inch.

These machines are now in use on the main gates of the upper lock at Gatun, and will later be used on all of the gates in the three sets of locks. They were designed by the Foote-Burt Co. of Cleveland, Ohio, especially for this work, and the distinguishing features are great power, 9 speeds, from very slow for heavy drilling to very high for lighter reaming, and fixed spindles arranged to suit the uniform spacing of rivet holes in the lock gates. On test, one of the machines drilled 1 1-16-inch holes through 1-inch plate in four seconds, being at the rate of 15 inches per minute. It is estimated that each machine is capable of doing the work of five of the usual type of portable reamer.

The complete machines, mounted on four wheels, these latter, in turn, being mounted on bearings, were racked along by a hand wheel located in front. The spindles were elevated by another hand-wheel for this purpose, also located in front.



Rear View of Special Reamer for Lock Gate Construction, Panama Canal.



Front View of Special Reamer for Lock Gate Construction, Panama Canal.

INTERNAL GRINDING MACHINE.

AN internal grinder of interest to automobile manufacturers, makers of roller bearings, and to any manufacturer who has occasion to use such a tool, has recently been placed upon the market by the Brown & Sharpe Mfg. Co., Providence, R.I. It is known as the No. 22 Internal Grinding Machine and the two accompanying views show plainly many details in construction as well as its general characteristics.

Design and Purpose of Machine.

This machine is designed to meet the requirements of all varieties of internal grinding that can be revolved within its range. Holes from 2½ to 12 inches diameter and 8 inches deep can be ground, and the machine will swing 18 inches. With a special spindle, holes less than 2½ inches diameter, but not exceeding 12 inches deep, can be ground The machine is particularly adapted to grinding holes in hardened steel gears, cutters, collets, bushings and similar classes of work. Taper holes can be ground as easily and accurately as those that are straight; and work, such as the facing of recesses in automobile gears to obtain a bearing true with the hole, can be done without removing the piece from the machine.

The result of extensive experience in the construction and use of various kinds of grinding machines and of careful study into their particular requirements is evident in this design. The various parts are so arranged and constructed that extreme accuracy may be secured in work produced; efficiency and convenience being equally prominent features. In this machine, the work speeds and table feeds are completely

separated; an important factor in commercial grinding. By this arrangement it is possible to obtain a correct table feed for any work speed; thus, when it is desired to remove stock rapidly, a slow speed and fast speed are available. Both work and table feeds are started and stopped by a single lever located at the front.

All wearing surfaces are adequately protected; the ways of the bed being always covered and the oil holes protected from grit and dust. All screws, bolts, and nuts requiring frequent adjustments are hardened. The handwheels and levers for controlling the various movements are all placed at the front.

Spindle Speeds, Stand and Slide Details

An ample range of independent spindle speeds is obtained by the use of interchangeable split pulleys on the intermediate shaft at the back of the wheel stand, and an idler pulley is provided to keep an even tension on the belt and take up slack due to the use of pulleys of different diameters. Three split pulleys are furnished, providing for speeds from 3,990 to 7,300 revolutions per minute. The wheel stand and slide are both of heavy, rigid construction, capable of resisting vibration which would lead to inaccuracy in the work. The wheel stand swivels, thus permitting the spindle to be set at an angle when grinding the face of cutters or automobile gears. This feature is also convenient when a hole has been ground and it is desired to grind the face of the work before removing it from the machine. Transverse movement of the slide is obtained through a worm and wheel actuated by a hand-wheel at the front of the machine. When desired, an automatic cross feeding mechanism similar to that found on all B. & S universal and plain grinding machines, can be furnished.

Headstock.

The headstock, of rigid design and firmly fastened to the swivel table by means of bolts that slide in a T-slot, swivels, and can be set at any required angle; the amount of adjustment being indicated on the graduated dial on the base. The spindle is hollow and runs in bronze boxes provided with means of compensation for wear. It can be locked in position when removing the face plate, chuck, or an attachment.

Another valuable feature is the belt tightening device shown over the pulley. This consists of a small pulley mounted on a bracket that can be drawn forward or pushed back by means of a handle. When drawn forward, a tension is brought upon the belt, causing the spindle to revolve and drive the work, and when pushed back the spindle may be quickly brought to a stop for changing the work or easily revolved by hand when centreing a piece. A range of 12 work speeds, varying from 40 to 340 revolutions per minute is provided.

Sliding Table.

The sliding table is of rigid construction and its bearings are scraped to fit the ways in the top of the bed which are aligned with master straight edges. The travel of the table is automatic and entirely independent of the speeds of the work and wheel. It is controlled by adjustable dogs on the front of the table that operates against the reversing lever. The dogs can be raised and the table run beyond the reversing points without disturbing their adjustment; a valuable feature when withdrawing the work from the wheel. When the work is finished, the trip dog nearest the wheel is raised, the table then moves to the left until the power feed automatically disengages. It may then be moved farther away by the large hand wheel. After a new piece of work is put in, the table is moved up by means of the hand-wheel until the work nearly reaches the wheel when the power feed automatically engages again.

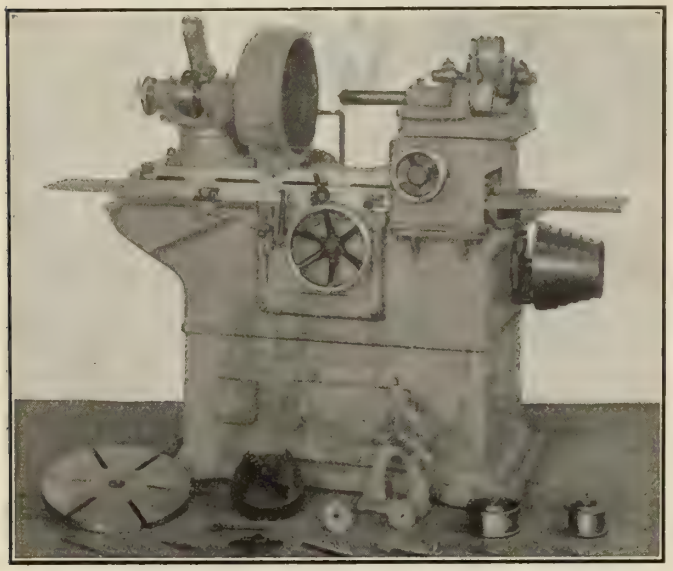
Provision for Wet Grinding.

The soda water is pumped from a tank located in the bed and is fed to the wheel through the hollow work spindle. The pump consists of a simple fan revolving in a case, and, as it is immersed at all times, no packing is required. The tank is readily accessible for cleaning. The hood or water guard shown on the machine is furnished for covering the work.

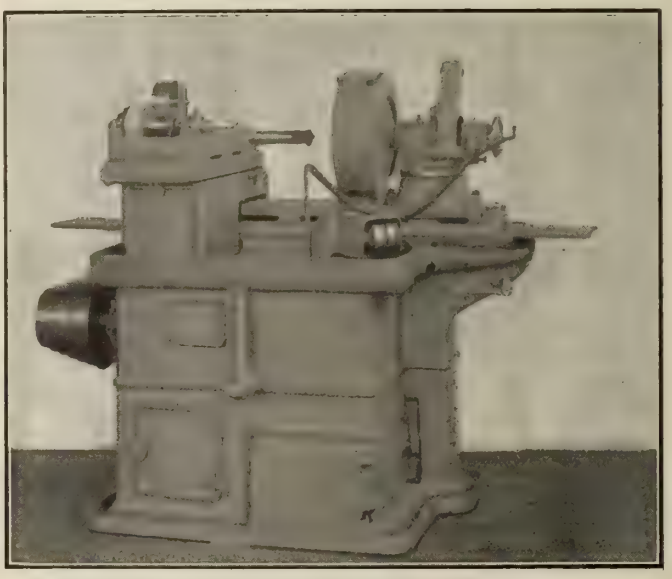
In other details the construction of this machine differs but little from that of B. & S. universal type. The swivel table, however, pivots on a stud located beneath the headstock, making a long leverage from that point to the end; thus enabling very fine adjustments to be made in setting to grind straight or in bringing a taper to the exact angle after the headstock has been set as closely as possible by the graduations on its base.

There are six changes of table feed, varying from 15 to 48 inches per minute, available for any work speed.

The equipment furnished with the machine is shown about the base in the front view, and also includes the overhead works which are not shown.



Brown & Sharpe No. 22 Internal Grinding Machine.



Brown & Sharpe No. 22 Internal Grinding Machine.

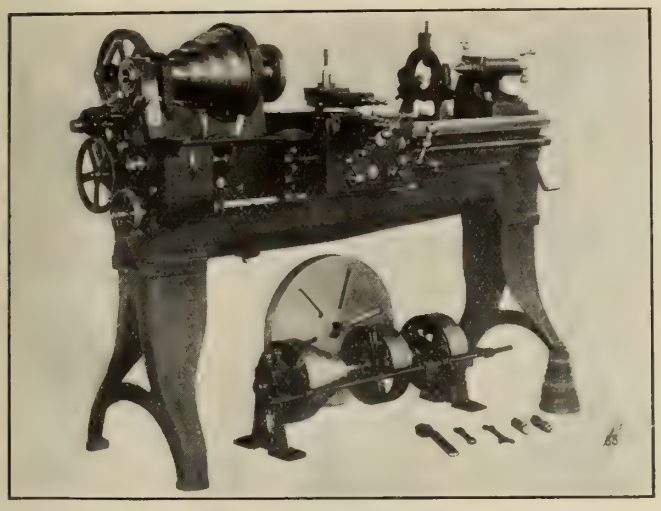
14-24 INCH SLIDING EXTENSION GAP ENGINE LATHE.

THE Barnes Drill Co., Rockford, Ill., have recently put on the market a 14-24-inch extension bed gap lathe, particulars of which will doubtless be of inter-

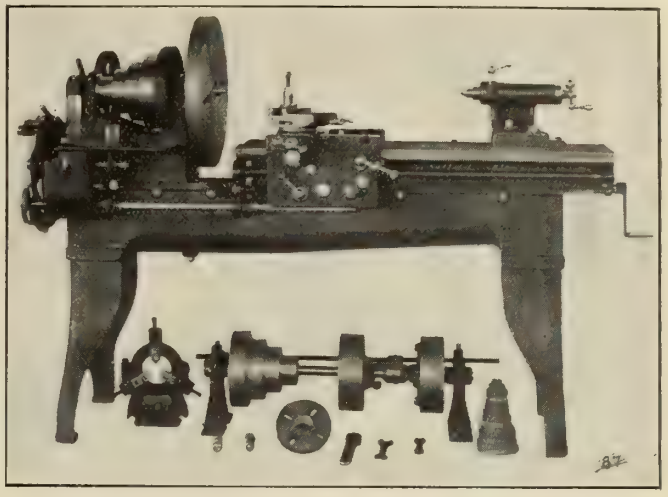
est to our readers. Notable improvements over the firm's 13-22-inch machine include a larger spindle—2 15-16-inch, taking 1½-inch stock through same; cone diameter increase to give strong driving power; geared feed box giving six quick changes of geared feed; strengthening of compound parts and heavier tail stock spindle.

The lathe is a strong, well built tool adapted for automobile garage and general repair work, and is being used extensively for these purposes. It also makes a very convenient tool for fitting and assembling work in factory machine shops.

A self-contained motor drive is a feature of the equipment and for this purpose a 2 h.p. motor, running 1,200 r.p. m., is recommended.



14-24 inch Sliding Extension Gap Engine Lathe.



14-24 inch Sliding Extension Gap Engine Lathe.

and will handle a wide range of work. The sliding top bed will be found an indispensable feature for many jobs, especially on general repair work, because it permits you to swing pieces of larger diameter through the gap, and of greater length between centres, than is possible on an ordinary 14-inch lathe.

This machine has the necessary strength and power to turn full diameter of swing in the gap, and at the same time is free from any awkward or objectionable features for use when the gap is closed. A taper attachment when so ordered, is furnished at extra cost. The lathe is especially well

AUTOMATIC FEED WEDGE GRIP RIVET HEADER.

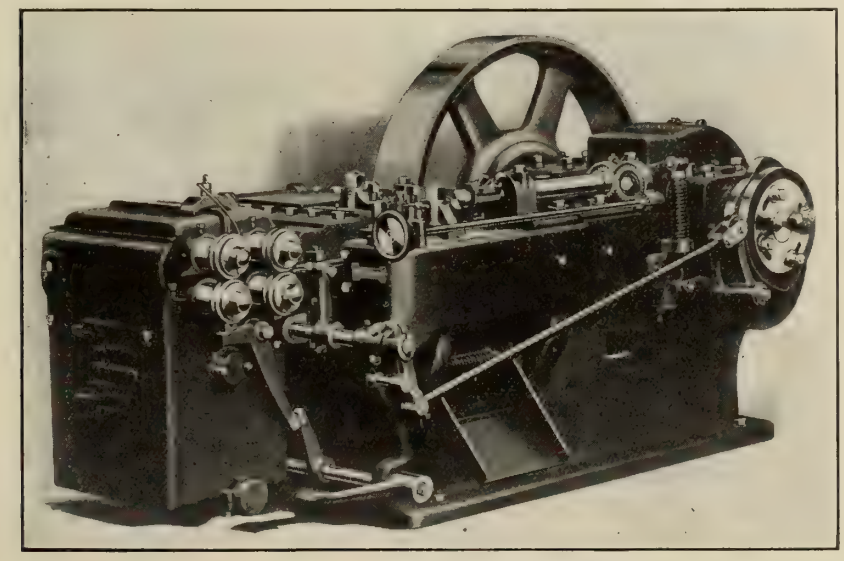
THE National Machinery Co., Tiffin, Ohio, originators and builders of bolt and nut machinery, are devoting considerable effort to the development of automatic and semi-automatic equipment of this type, with a view to eliminating the excessive manual labor required in the operation of rivet machines, bolt headers, nut tappers, etc. Experience shows that the operator is subject to great body fatigue, which results in decreasing his efficiency or productive capacity, and consequent losses in output.

We illustrate herewith a new design of automatic feed for National Wedge Grip Rivet Headers, which has recently been perfected by this company, and which embodies some novel features. In this machine, long rods in mill lengths, taken on the initial heat from the finishing rolls or reheated in special long furnaces, are started into the feed rolls by the operator; the rod being advanced automatically, a blank sheared and headed, and a finished bolt or rivet ejected at each revolution.

Single-blow bolts, rivets, track bolts, or any type of "single-blow" work can be made in this machine, and the "Wedge" gripping mechanism insures a product free from swollen shanks or objectionable fin along the body, as the dies cannot "spring" or give during the upsetting. The feed rolls are chilled castings and are water-jacketed; thus maintaining an even temperature and insuring minimum wear on the feeding surface, hence positive and uniform "feeding."

A new type of stock gauge is employed which is designed not only to allow rapid and minute adjustment while the machine is in operation, but also to eliminate "spring" and thus secure high uniformity in the quality of the product. In plants where these headers are operating, outputs are secured 50 to 100 per cent. larger than obtainable on the hand-feed machine, and due to the accuracy and uniformity in "feeding;" a better quality of output also is secured on the automatic feed header.

The Wedge grip rivet header with automatic feed is built in 1, 1¼ and 1½ inch sizes, illustrated descriptions of which are to be found in Circular 1016, issued by the National Machinery Company.



Automatic Feed Rivet Machine.

MOULDING A CONDENSER SPRAY PLATE.

By J. H. Eastham.

THE circular casting shown in plan and cross section views at Fig. I. was required for condensing purposes; being in effect a plate pierced by 3,500 holes, each tapering from 5-16 to ¼-inch. Six ribs, cast on the upper side, to strengthen the piece, tapered in depth from 2½ to ¾-inch. The small holes running through the casting each terminated on the under side in a small boss; ¼-inch metal being allowed round each hole.

The cost of a complete pattern being considered out of the question, a corebox, one-sixth section of the full radius,

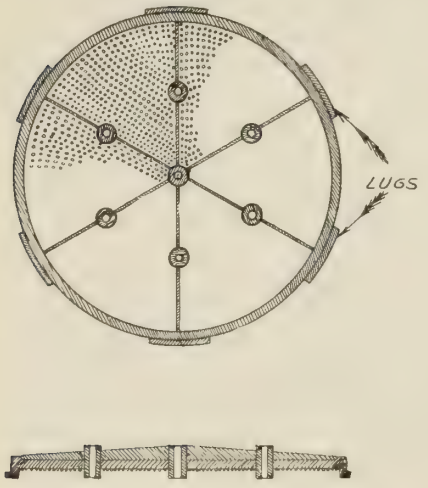

Fig. 1—Condenser Spray Plate.

was first made; each slab or section of core being indented by some 580 small prints, in which to paste the cores to form the small taper holes above mentioned. A small corebox to turn out four of the round cores at each operation was handed to a boy, who, after making the 3,500 needed, dried and pasted them into the prints in the slab cores. The six sections were then shelved till needed by the moulder. The sweep shown at A, Fig. 2, was fitted to a spindle, and used to strike out a bed on which to lay the rib pattern and ram up the top impression; the sunk parting indicated at B, being necessary, as the cope part, C, was of ordinary straight barred type.

In Fig. 3, the rib pattern with rough battens nailed on to avoid breakage or ramming out of shape, is shown laid on the parting, with empty cope in position ready for ramming. One inch of facing sand was spread inside the arms; gaggers and wooden soldiers being employed to carry the lift. The cope was then rammed-up and staked in the usual way. The ribs were hoisted away with the top part, by means of a couple of wood screws, as is usual in the case of loose

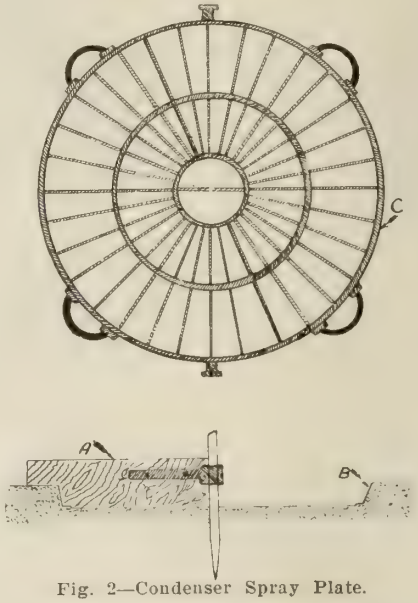

Fig. 2—Condenser Spray Plate.

pieces or coreprints on the upper side of patterns.

The cope being removed and the mold drag dug out, the strickle, with additional piece screwed on, was again used to sweep out the extra depth required as coreprint, the sloping parting being kept good, as shown at F, Fig. 4. The six lugs or short flanges shown in Fig. I. were now bedded-in and drawn inwards from one pattern, the mould overhanging them being well nailed to prevent any crush when trying on the cope. The bottom mould was now ready for the section cores. These having been set, the

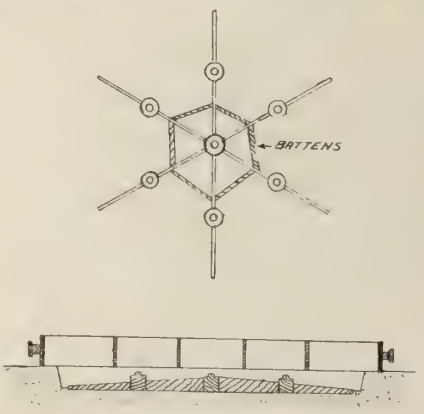

Fig. 3—Condenser Spray Plate.

cope was scraped to remove any irregularities caused through ramming; the few protruding soldiers knocked back below the surface, the face sleeked over, the arms drawn out and finished, and plumbago blacking spread over the whole surface.

A wash over with molasses water and a little skin drying were now considered advisable. The mould was, therefore, suspended over a fire of shavings for this latter purpose, whilst the 2-inch round cores through the seven bosses were placed in position. The cope was next tried on, and being found to touch the small cores all over the mould fairly accurately, was closed finally, weighted, and the piece cast without mishap.

One-third of the plan view of the closed mould at G, Fig. 4, is left open to

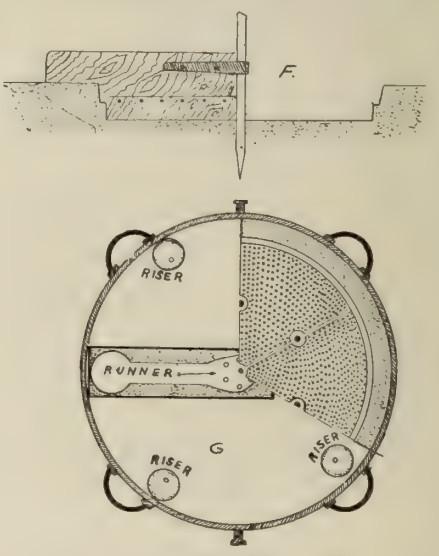

Fig. 4—Condenser Spray Plate.

show two of the section cores in position. the remainder showing the runners and risers. A small round gate on each of the six cross ribs spread the metal evenly and quickly, and minimized the risk of the small cores being washed away or broken through a flow of metal from any particular point. The weights were not removed from the mould till the following morning; this precaution keeping the casting quite straight, little chipping being required beyond the punching of the cores from the small holes. This operation was accomplished by a couple of men in a few hours.

CONTEMPORARY CHANGES.

Owing to the fact that the demand on Mr. Henry M. Lane's services for professional assistance along engineering and metallurgical lines in foundry practice has become very great, he has ten-

dered his resignation as one of the editors of "Castings" and "Wood Craft," and will in the future devote his entire time and knowledge to expert consulting work in foundry practice. His long experience in solving problems in this line makes his well-known ability of great value to any foundryman who desires expert service. Announcement of Mr. Lane's successor will be made in due course.

FLASKS FOR JAR RAMMING MOULDING MACHINES.

By J.F.G.

THE accompanying sketches illustrate a style of flask which is so constructed that it needs no bars to carry the sand, (E), and for this reason, there is not only much time saved in changing

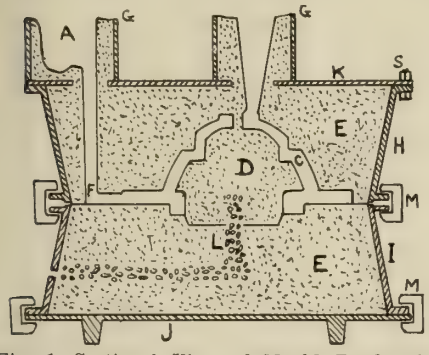

Fig. 1—Sectional View of Mould Ready for Pouring, Showing Mould, Core, Riser and Gate.

bars for different shaped patterns, but also the first cost of making these and their patterns. Now, as the flasks (H) and (I) are made tapered, so that the sand cannot slide out, we must have the top plate (K) to hold the sand when the cope is turned upside down to be finished, and also to keep the pressure of metal from pushing the sand up during the pouring operation. The top plate (K) will be the same as the bottom plate (J), except openings (R) and (Q) for gate (F) and riser (B); or as many holes as there are gates and risers required. It is also the best practice to cast holes in the top plate of the cope and oblong holes in the plate, as shown at (T). Further, it is safer, just as quick, and does not necessitate making the trunnions (N) as long as they would need to be if clamps (M) are used on the top part of the cope and bottom part of the drag. These flasks can be used up to a very large size on dry sand work, especially when the cope part of the mould is arch-shaped.

The ordinary iron boxes opened on two ends for building up runners and risers are indicated at (G), and (C) shows the cavity to be filled with molten metal. The core is shown in position inside the mould at D, and A represents the pouring basin.

FIRE PROTECTION FOR FOUNDRIES.

AT the New England Foundrymen's Association meeting held in Hartford, Conn., on May 8th, a committee was appointed to look into better fire protection and insurance rates for foundry properties. The chairman is

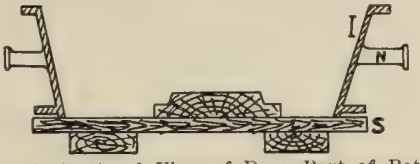

Fig. 2—Sectional View of Drag Part of Pattern Attached to Board with Drag Part of Flask, Ready to Place on Jarring Machine.

Bartlett M. Shaw, of the Walker-Pratt Mfg. Co., and the other members are George P. Aborn, of the Blake & Knowles Steam Pump Co., and Henry A. Carpenter, of Providence, R.I. Both Mr. Shaw and Mr. Carpenter are past presidents of the association. It is the intention of this committee to study the whole subject of fire protection in foundries, with particular reference to improving conditions and thus securing better insurance rates. The main object, however, has actual saving of property back of it rather than a mere adjustment of rates, for it is realized that the true purpose of any such study is to lessen the destruction by fire of created properties.

LET THE FOUNDRY ASSERT ITSELF.

MR. H. M. RAMP, superintendent of the Modern Foundry Co., in his address before the Superintendents' and Foremen's Club, Oakley, Cincinnati, Ohio, said that "while the foundry deserves much criticism and correction, it

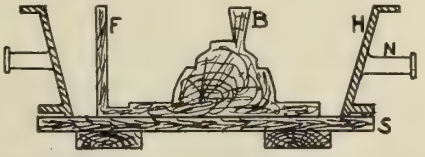

Fig. 3—Sectional View of Cope Part of Pattern Attached to Board with Cope Part of Flask Ready to Place on Jarring Machine.

has never had the attention, the brains, the research work, or the finances poured in upon it that the machine end of the iron industry has had to elevate and develop its possibilities. It has been considered more as a necessary evil than as a branch of the business that could be mastered, developed and controlled. The foundry, until the last few years, has been the last place to receive improvement and advice, and it is not as yet burdened with a load of either.

"The individual who entered the foundry as a life's business was always regarded as sinking his intellectual or mechanical abilities, if he had any. The foundry has been demeaned and often referred to as a place where the qualifications are 'a strong back and a weak mind,' and yet there is no business under the canopy of heaven that requires greater judgment and a more thorough knowledge of fundamental principles than the art of molding. When properly done it most certainly deserves to be classed as an art, and yet this is the atmosphere in which foundries were developed and foundrymen made until the past few years, while the machine shop was commanding the gray matter and finances of the brightest men, everywhere available.

This prejudice against the foundry in the past, as a place of dirt and grime fit only for occupation by hewers of wood and haulers of water, has done much to retard the development of the foundry business and to keep the bright, ambiti-

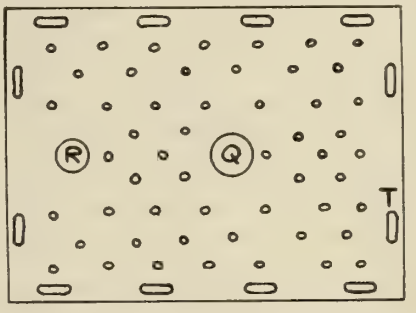

Fig. 4—Top Plate Showing Holes Through Which Riser and Gate Pass, and Oblong Holes for Fastening with Bolts to Flask.

ous and energetic men from mastering its science.

These are not, however, the only reasons why the foundry fails to give the machine shop what it asks. When the machine shop seeks to improve its tools or methods, it does not put blacksmiths or candy makers on the job—it uses the best educated brains and experience in the machine business that money can buy; yet too often, the pattern, the very foundation of the foundry's work, is constructed as the designer, the pattern foreman or the engineer directs, without even consulting the experience and preference of the foundry, and in as great a measure as this prevails just as great is the handicap placed upon the foundry."

THE PEASE FOUNDRY CO.

The new plant of the Pease Foundry Co., to be erected in Brampton, Ont., will comprise 11 buildings, all one storey except the office building, which will have two stories, giving an aggregate floor space of 137,000 square feet. The buildings include a foundry, warehouse, shipping room, blacksmith shop, machine shop, core room and ovens, rumbling room, pattern shop, pattern vault and dome, and tin shop for the manufacture of furnace casings.

Trade Gossip.

Mr. Alex. Gibb, agent for Beardshaw's steels and drills, has removed his place of business from 13 St. John St., Montreal, to St. Nicholas Bldg.

H. L. Peiler & Co., of Montreal, have opened a special department to deal with the question of combustion, forced draught, gas and oil engines. L. H. Bacque is engineer in charge of this work.

Mr. Alfred Still, an English engineer, and author of a number of standard works, has been appointed chief engineer at the mines and hydro-electric plant of the Algoma Steel Co., in the Michipicoten district of Canada.

Reported Merger.—It is reported that the Thomas Davidson Manufacturing Company, of Montreal, the Kemp Manufacturing Company, of Toronto, and the McClary Manufacturing Company, of London, are again in negotiation towards a consolidation of interests.

Canadian Steel Foundries.—The output of the Canadian Steel Foundries Co. will double present capacity by the middle of June, as on the 15th of that month its new $1,000,000 plant at Longue Pointe, Montreal, will start operations.

Pratt & Letchworth Co.—The resignation of C. W. Sherman, general manager of the Pratt & Letchworth Co., was accepted at the meeting of the board of directors of that company, held in Buffalo recently, and took effect June 1. Mr. Sherman retires to organize a company to operate a steel foundry at Hamilton, Ont.

The Belgo-Canadian Steel Co., Ltd., with a capital of $550,000, was incorporated recently to manufacture steel and iron castings. The head office and foundry are to be in Montreal and will be in operation shortly. The officers of the new company are: President, Alphonse Baillot; vice-president, L. G. Beique; sec.-treas., F. A. Beique.

Messrs. Baillot and L. G. Beique are well known to the foundry trade, being directors of Baillot's Gas and Steel Machine Co., Ltd., which has recently manufactured the equipment for several large new foundries.

The Foss & Hill Machinery Co. have removed from 329 St. James St. to new premises at 344 St. James St., where they will have better facilities for carrying a stock of the lines they handle. This firm has recently taken the agency of the J. I. Case Co., of Racine, Wis., for road rollers and contractors' equipment.

Plastics, Limited, of Toronto, have appointed the General Supply Company of Canada, Ltd., Ottawa, sales agents in Manitoba, Alberta and Saskatchewan for "Bakelite" valve discs and pump valves. This business will be handled from the Winnipeg branch. "Bakelite" valve discs and pump valves are being widely recognized by the trade.

The Magnolia Metal Co. has issued new booklets in English, Spanish and Portugese, containing testimonials and tests describing the value and uses of Magnolia Anti-Friction Metal, and giving full directions for pouring. These books are intended for general distribution, and anyone can obtain copy by addressing the company.

The Stahlschmidt Tool Co., of Canada, Ltd., has just been incorporated under Dominion charter. The officers are: President, E. F. Walter; sec-treas., R. Gnaedinger, and general manager, E. K. Watson. Mr. Watson is admitted to be among the most competent tool and hardware authorities in Canada. This company is a branch of a German house of the same name, situated at Cronenfeld, near Solinger. They will handle high speed steel, tool steel and small tools of all kinds.

The Smart-Turner Machine Co., Ltd., Hamilton, have recently booked the following orders:—Joseph Battle, Thorold, Ont., Duplex Pump; The Western Construction Co., Courtright, Ont., Duplex Pump; Corporation of Dauphin, Man., pump for waterworks extension; The Wolverton Milling Co., Wolverton, Ont., Rotary Force Pump; The National Land Fruit & Packing Co., New Toronto, Duplex Pump; H. Webster, Norwich, Ont., Triplex Power Pump; The Keewatin Lumber Co., Keewatin, Ont., Duplex Pump; The Niagara Navigation Co., Duplex Pump; R. M. Breckenridge, Burlington Junction, Triplex Power Pump; Geo. Frid & Son, Hamilton, Standard Duplex Pump.

The J. W. Paxson Co., Philadelphia, Pa., have issued their Bulletin No. 26, which deals in a comprehensive way with the cupola, blower, cupola lining and cupola practice in general. Special reference is made to the Paxson-Collian cupola, as exclusively manufactured by this firm. These are built in sizes having capacities from ½ to 25 tons per hour, the former size being designed for the use of research laboratories, technical schools, etc. The company own quarries from which they are prepared to supply mica-schist in car load lots. This material is meeting with increasing favor for patching cupola linings; being as easily applied and lasting much longer than fire brick.

The bulletin contains many useful hints on the care, preparation and operation of cupolas, and will be gladly sent to parties interested.

Harker & Kembley, brass founders, brass finishers and general machinists, 81 Peter Street, Toronto, report a steady development and increase in their business up to May of this year; that month marking the completion of one year's establishment of the plant. We understand that steps are being taken to extend the shop, and opportunity will be taken to still further add to the tool and other equipment by the installation of the latest machinery available. Mr. Harker was for 24 years foreman of the brassfinishing department of Wilson & Cousins, Toronto, while Mr. Kembley has been foreman of the J. J. McLaughlin Co., brass finishing department, Toronto, and inspector with the Westinghouse Machine Co., Pittsburg.

The Van Norman Machine Tool Co. has been incorporated with a capital stock of $400,000, with the following officers: President, F. H. Page; treasurer, C. J. Wetsel; vice-president, C. E. Van Norman; secretary, F. D. Van Norman. Mr. Page is president of the National Equipment Co., builders of candy machinery, and Mr. Wetsel has been treasurer and general manager of the Baush Machine Tool Co. for the past eight years.

The Van Norman Machine Tool Co. will carry on the business formerly conducted by the Waltham Watch Tool Co., and will build the Van Norman line of "Duplex" milling machines, Universal bench lathes, "High Speed" grinding machines, etc., covered by patents of Charles E. Van Norman and of Fred D. Van Norman.

Charles E. Van Norman and Fred D. Van Norman are Canadians, being old Hamilton, Ont., boys, who started the tool manufacturing business in Springfield, Mass., known as the Waltham Watch Tool Co. The new Van Norman Machine Tool Co. is the outgrowth of this business.

The Humber Machine Co. — About three years ago the Humber Machine Co., Humber Bay, Toronto, took over the machine shop of Mr. W. J. Nesbitt, who, prior to that time, had been conducting a small machinery repairing business with a number of west-end manufacturing concerns. After a long up-hill struggle, in which were met many obstacles and reverses, they have succeeded in building up a live business in general machinery repairs, and the manufacture of trade specialties and special machinery to order, and it has now been found necessary to treble the amount of floor space in order to take care of increasing orders. Much of this highly satisfactory state of affairs is due to the fact that during the past six months the firm have gone into the manufacture of a special line of machinery to meet the demand of one of Canada's fast growing industries, and the success in this feature has enabled them to extend business connections across the entire Dominon.

A WINNING HAND

THE Foundryman who uses **Stevens' Genuine East India Plumbago,** or **Ceylon Lead,** always plays a winning hand. He is betting on a sure thing.

I import this article direct from India, because it is absolutely the best plumbago produced in the workshop of Dame Nature.

It's use enables the foundry to do the work sometimes left for the machine shop to finish.

I manufacture everything used in a Foundry and in a Polishing and Electroplating Department.

In buying from me you are buying from first hands.

It costs as much to sell one thing as to sell them all. I sell them all for a small slice of profit. I take the small slice and give you the rest.

Take Time to Write Me a Letter.

FOUNDRY AND MACHINE SHOP.

Sarnia, Ont.—The municipal council have negotiations on with the management of a large steel manufactory. They have offered one acre of land free.

Ottawa, Ont.—It is reported that a new plant for the manufacture of wire cloth is to be built in Ottawa, Canada, by John R. Buchanan of the Appleton Wire Works of Appleton, Wis., manufacturers of the same line of goods. Mr. Buchanan has severed his connection with this company and is organizing for manufacturing in Canada.

Calgary, Alta.—Within a month or two, work will be started on the building of a railway to the property of the Alberta and Canadian Iron Syndicate, 25 miles west of Okotoks. When railway is completed, a smelter and 400 ton stamp mill will be erected. The whole project will involve an expenditure of $5,000,000. P. Burns is behind the venture.

Port Mann, B.C.—A car building and accessories plant is about to be established at Port Mann, B.C. The plant will include a cast steel foundry and rolling mill. It will cost $1,500,000 and will employ about 1,200 men.

Sault Ste. Marie.—It is announced that henceforth the Lake Superior Iron and Steel Company located at Sault Ste. Marie, Ont., will be known as the Algoma Steel Corporation Limited. The capital is increased from $1,000,000 to $30,000,000.

St. Mary's, Ont.—The Maxwell Machine Works at St. Mary's, Ont., are enlarging their plant by an additional storey to their carpenters' shop.

Galt, Ont.—The Malleable iron foundry located at Galt, Ont., will shortly add an extension. The new building will be 60 x 60 and will be of steel and brick.

Port Colborne, Ont.—The Buffalo Furnace Works recently executed with the Minister of Railways, a lease of a part of the reserve on Welland Canal at Port Colborne, Ont. The company plans to expend $210,000 in the development of its industry there.

Victoria West, B.C.—The Canadian Pacific Railway is calling tenders for constructing machine shops, roundhouses, turntables, and repair tracks at Victoria, West, B.C.

Regina, Sask.—The Garden City Feeder Company, Limited, manufacturers of agricultural machinery is about to establish at Regina, Sask. The company is just starting up and is incorporated with a capital of $100,000.

Fort William, Ont.—It is reported that J. J. Hill and associates have purchased two miles of lake front near Fort William, Ont., as a site for steel works, foundry and blast furnace.

Gravenhurst, Ont.—Fred J. Brown, founder of the Northern Ontario Engineering Works at Cobalt, Ont., has started the erection of a machine shop for the repairing of gasoline, oil engines, etc.

Belleville, Ont.—The Marsh and Henthorn foundry company will have extensive and up-to-date buildings at Belleville, Ont. The machine shop, which will be the principal building, will be 142 x 65 feet; the boiler shop 122 x 36 feet; the blacksmith shop 60 x 35; and the pattern shop 40 x 60 feet. F. H. Herbert, of Toronto, is the architect.

MUNICIPAL.

Melford, Sask.—The ratepayers are about to vote on two by-laws; one to raise $60,000 for waterworks construction and another to raise $30,000 for cost of sewerage construction.

Collingwood, Ont.—The people of Collingwood will soon have the opportunity of voting a bonus to the Canadian Vending Machine Company, about to commence operations there.

Battleford, Sask.—Among the many civic improvements taking place at Battleford, Sask., is the construction of the sewerage system and the waterworks, which involve an outlay of $100,000.

Kelowna, B.C.—The following by-law was recently passed by the ratepayers:—$7,000 waterworks extension.

Vernon, B.C.—The following by-laws have received the sanction of the ratepayers:—$7,500 for municipal building; $40,000 for extension of waterworks system.

St. Catharines, Ont.—The burgesses sanctioned by-law, recently submitted, calling for a bonus of $4,000 to the Canadian Warren Axe and Tool Company.

Prince Albert, Sask.—The ratepayers ratified the following by-law:—To raise $73,800 for extensions of water mains.

Delta, B.C.—The ratepayers passed two by-laws, one to raise $15,000 for municipal building and another to raise $4,000 for purchase of road-making machinery.

Oakville, Ont.—The town council has decided to expend $20,000 on the Water and Light Commission.

Moose Jaw, Sask.—The burgesses passed the following by-law:—$60,000 for high pressure system.

Moncton, N.B.—The ratepayers may be called upon at any time to vote $3,600 for a motor truck.

Fort Frances, Ont.—The ratepayers recently ratified by-law to grant a bonus of $25,000 to the Fort Frances Power Company.

Brandon, Man.—The ratepayers passed the following by-laws:—$1,500 for street improvements; $12,000 for right-of-way for the Brandon Transfer Railway; $33,000 re new firehall; and $100,000 re cost of improvement of the waterworks system.

Merritt, B.C.—The property owners ratified the following by-laws:—To raise $40,000 for erection of pumping station; $20,000 re installation of electric light plant; $10,000 for building of sidewalks and $3,000 re purchase of site for a public school.

St. Thomas, Ont.—The board of trade has decided on the expenditure of $4,000 re encouragement of new industries.

Duck Lake, Sask.—The by-laws aggregating several thousand dollars were passed by burgesses. The by-laws involved an expenditure of $4,000 for flour mill and $6,000 for new town hall.

Port Dalhousie, Ont.—The burgesses voted in favor of by-law to raise $10,000 re the cost of repairing the electric lighting system.

North Vancouver, B.C.—The North Vancouver Gas and Coke Company are about to start construction of their works at North Vancouver, B.C. They request certain concessions from the city, and are awaiting the sanction of the by-law, placed before the ratepayers, granting same. The company is incorporated under the above title, with subscribed capital of $200,000.

South Vancouver, B.C.—The local board of works has ordered road improvements on an elaborate scale, involving an expenditure of $132,967, also the purchase of steam shovels, etc.

ELECTRICAL.

Orangeville, Ont—The Dufferin Light and Power Company's property at Orangeville, Ont., has been sold to J. M. Milburn, of Owen Sound, for $46,000.

Hydro-Electric Power Co.—Five more towns in the northern part of Ontario will be served by the Hydro-Electric Power Co., viz.: Barrie, Staynor, Collingwood, Coldwater and Elmvale.

Saskatoon, Sask.—H. M. E. Evans, of the Saskatoon Power Company, reported to the council that 14,000 h.p. could be generated at total cost of $2,200,000, and the council are considering the situation.

Sturgeon Falls, Ont.—The Nipissing Electrical Repair Company has recently been established at Sturgeon Falls, Ont. H. J. Hopes is in charge.

Caledonia, Sask.—The village council are about to secure the installation of the Hydro-Electric power system.

Melford, Sask.—The burgesses of Melford, Sask., are about to vote on a by-law to raise $35,000 for the installation of an electric light plant.

Niagara Falls.—The City Council has received permission from the Ontario Government and the Hydro-electric Power Commission to proceed with the construction of a new power house and pumping station, which, from an engineering point of view, will be a unique and interesting project. The plant will be located on the Canadian side of the upper river, several hundred feet from the crest of the Falls, in a chamber excavated out of solid rock and at the bottom of a shaft 125 feet deep on a level with the lower river. The object is to remove the existing power house and pumping station near Table Rock, which is not only unsightly to tourists, but is also inefficient and inadequate. It is now being used to pump water for the city, and the latter is buying power for lighting purposes from a private company. The existing plant was frequently choked by ice in winter, and was found incapable of maintaining a normal service either of water or power. With the new 1,500 horse-power plant the city will get an uninterrupted supply of both, and will be in a position to furnish power both for street lighting, pumping and for factories. The principal factors in the scheme are a 120-foot penstock, eight feet in diameter. The water will be carried down through this long tube, which will be of steel construction, into the turbines. Ice and surplus water will be diverted through an underground channel into the lower river, thus eliminating trouble from frazil ice. Before going ahead with the work the Council will have to secure permission from the Queen Victoria Niagara Falls Parks Commission, who, it is believed, will readily consent to the proposition. The members of the Council were in Toronto recently, conferring with the Ontario Government.

GENERAL MANUFACTURING.

Portage la Prairie, Man.—The Stephens Brick Company has completed arrangements for the erection of another brickyard. The new plant will have a capacity of 50,000 bricks per day.

Guelph, Ont.—Messrs. Grant & Armstrong have secured the sole agency for the Royal Spring & Bedding Co., in Canada and plans are about completed whereby they will commence at once to manufacture the Ingle patent bed spring and bedding line.

Calgary, Alta.—A carriage factory is about to be established in East Calgary by J. Wetmore and Company. The shop promises to be the largest west of Winnipeg and at the start will employ 25 men.

Winnipeg, Man.—Three buildings owned by Tees and Persse and used for storing stoves and furnace of the Waldon Company were recently destroyed by fire. The damage done amounted to $45,000; two-thirds of which is covered by insurance.

Calgary, Alta.—A new clay producing plant is about to be established, to be known as the Tregillus Clay Products Company. It will be a close corporation with a capital investment of $500,000; and will employ 200 skilled hands, although it is expected that ultimately as many as 500 men will be employed. W. J. Tregillus is behind the movement.

Medicine Hat, Alta.—An agreement has been reached through Mayor Spencer whereby Dr. Wright of Spokane, Wash., is about to locate a factory in the city for the purpose of manufacturing chalk. The capitalization is placed at $25,000 and the plant will employ 25 men; later to be increased to 100.

Stratford, Ont—Fire gutted the factory of the Tolton Manufacturing Co. recently. The roof was destroyed and the furniture and machinery damaged by water. The loss is fully covered by insurance, and the cause of the fire was an overheated stove.

Camrose, Alta.—The tannery owned by Francois Adam has been burned down. The total loss is about $25,000 which is partly covered by insurance.

Moose Jaw, Alta.—It is reported that the Federal incorporation of the Canada Flat Fibre Company, Limited, is about to start operations in the prairie provinces for the manufacture of paper.

Toronto, Ont.—The bed factory of the Anchor Manufacturing Company was partly destroyed by fire a short time ago. The loss caused is about $20,000 which is fully covered by insurance. It is understood that a new factory will shortly be erected by the company to cost about $35,000.

Espanola, Ont.—The Spanish River Pulp & Paper Company have started operation here with two machines. Both have a capacity of 100 tons of newspaper material and 170 tons of pulp material daily. Provision has been made so that the mill capacity can be readily doubled at minimum capital expenditure.

Crabtree Mills, Que.—The paper mills of Edwin Crabtree & Sons, Limited, have been completely destroyed by fire. The damage, amounting to from $65,000 to $70,000, was fully covered by insurance. The company are making arrangements to construct new mills at once.

Walkerton, Ont.—A biscuit factory is about to be established here. It, at first, will employ from 8 to 10 men, and will be ready to start at an early date. Robert Smith and John McCartney are behind the venture.

Stratford, Ont.—Danford Elk Shoe Company, Limited, of Windsor, Ont., have purchased a factory on William Street and will

commence at once the manufacturing of elk shoe leather. The promoters are:—D. M. Ferguson, Robert McEwen, J. A. Davison, C. S. Macpherson and W. C. Dunford.

Toronto, Ont.—The Keens Manufacturing Company, makers of whitewear, are about to erect a factory on Spadina Avenue.

Danville, Que.—The factory of the Dominion Novelty Company was burned to the ground recently. Damage was done to the extent of $25,000. Spontaneous combustion is the theory offered as likely cause.

St. John, N.B.—It is now definitely understood the Gibson timber land and property will be taken over by the syndicate of American capitalists of whom Senator Jones is leader. The new company will manufacture pulp and paper.

Transcona, Man.—Operation of the Dominion Tar & Chemical Company's works at Transcona, Man., are about to commence. The works will employ about 100 men; to be increased to 150 in a short time.

Brantford, Ont.—A fierce fire which caused damage to the extent of $65,000 broke out at the Farmers' Binder Twine Factory recently. It is supposed to have been caused by lightning. The loss is mostly covered by insurance.

Guelph, Ont—Tenders are being called for the erection of a three storey warehouse by the Guelph Carpet Mills Company at Guelph, Ont.

Toronto, Ont.—The establishment of a hundred-ton capacity pulp mill at a cost of about $500,000 and the erection of a hundred-ton paper mill at the direction of the Government is about to take place at Toronto, Ont. Tenders are invited for same.

Brandon, Man.—Fire recently destroyed the Maple Leaf Milling Company's elevators at Brandon, Man. The total loss, which is covered by insurance, is estimated at $60,000.

Wetaskiwin, Alta.—The Vulcan corporation is about to erect an automobile factory at Wetaskiwin, Alta. It will cost about $1,500,000 and will be the largest enterprise of its kind in Canada.

Seaforth, Ont.—W. J. Duncan, legging manufacturer has notified the local board of trade that, on account of his present quarters being too small for his increasing business, he would move to Stratford or London unless he received grant of a suitable building. The board recommended the purchase of the Grip Hotel property, to be paid for by Mr. Duncan in fifteen annual instalments.

Fort Frances, Ont.—An agreement has been reached between the town and the Minnesota and Ontario Power Company whereby the company agrees to build a 100 ton pulp and paper mill and to operate same.

Greenwood, B.C.—A cannery and fertilizing plant to cost $300,000 will be built on the opposite shore of Tuck's Inlet; work to begin as soon as site and plans are prepared.

Guelph, Ont.—At a recent meeting of the Board of Directors of the Dominion Co., a new industry starting up, it was decided to to call for contracts for the new building as soon as specifications have been drawn up.

Cobourg, Ont.—Martin Jet and Company of this place, have secured the contract for the new factory for the British-Canadian Canners at $35,000 exclusive of machinery, etc.

Guelph, Ont.—The Colonial Knitting Company, Limited, has started operations and promises to be a great asset to the city of Guelph.

Berlin, Ont.—President S. Nordheimer, of the Foster-Armstrong Piano Co., submitted a proposition to the town which will be taken up by Industrial Committee. The substance of the proposition is that if the company can get a $1,500 loan from the town they will in turn erect a 200 by 60 feet building and employ 70 hands.

London, Ont.—T. Dexter and Son will abandon their mill on the Thames and construct a mill in East London to be operated by Niagara power.

Calgary, Alta.—The Industrial and Development Bureau of Calgary, announce that Craig & Rose, Limited, of Edinburgh, Glasgow and London have decided to locate their Canadian branch here. This is one of Great Britain's largest print manufacturing firms.

Parry Sound, Ont.—A new industry has been started up within the past few weeks, and promises to be of some importance. The industry is known as The Flempol Manufacturing Company, Limited, and is capitalized at $100,000. Furniture polish will be manufactured.

Warwick, Que.—The Dominion Comb and Novelty Company's factory was burned lately and sustained a loss of $30,000. Insurance was $12,000.

Glassy Lake, Alta.—Fire totally destroyed the 30,000 bushel elevator of the Medicine Hat Milling Co. $18,000 is the estimated loss, partly covered by insurance.

Niagara Falls, Ont.—The burgesses have recently passed a by-law authorizing a grant

of $3,000 to E. T. Pollard for a site for his new industry.

Blyth, Ont.—The ratepayers recently ratified a by-law to grant a loan of $5,000 to the Blyth Flax Mill Company.

Medicine Hat, Sask.—Two by-laws are about to be brought before the people. Both are to raise money for Industrial sites.

Fort William, Ont.—The "Arena" Rink, one of the largest in Ontario, was burned to the ground quite recently. The loss is placed between $30,000 and $35,000; covered by insurance.

PLANING MILLS AND SAW MILLS.

Galt, Ont.—What is known as the old Scott planing mill, at Galt, owned by W. R. Osborne, has been sold to H. F. Bailey who will completely overhaul the building and machinery.

Pelican, Ont—It is reported that the Carthy sawmill at Pelican, Ont., has been completely destroyed by fire. No details are given.

Revelstoke, B.C.—Operations at the Dominion sawmills of Taft, Three Valley and Comaplix will begin at once. The mills will employ about six hundred men.

West Toronto, Ont.—The planing mill of Gibson, McCormack & Irving was swept by fire a few days ago. The damage amounted to $2,800.

Battleford, Sask.—The Battleford Overland Manufacturing Company propose erecting a two-storey factory 40 x 100 feet to be equipped with machinery capable of turning out all kinds of finished wood work. They are asking certain concessions from the town.

Victoria, B. C.—Damage to the extent of $80,000 was done by a fire which recently broke out in the plant of the Canadian-Puget Sound Lumber Company at Victoria, B.C. The chief loss to the company will be the destruction of the up-to-date machinery which was only recently installed.

Winnipeg, Man.—The lumber mills of Brown & Rutherford were completely destroyed by fire involving a loss of $200,000, of which, only $16,500 is covered by insurance.

North Vancouver, B.C.—Fire recently destroyed the saw and shingle mill of the Seymour Lumber Company of North Vancouver, B.C. The total loss was approximately $50,000.

Owen Sound, Ont.—The saw mill of the Carney Lumber Company was wiped out by fire recently and entailed a loss of $150,000, only partly covered by insurance.

Nelson, B.C.—It is reported that the Cascade mill of the Dominion Sawmills, Limited, of Nelson, B.C., will, this year, increase their output by six million feet over last year's output. This will make twenty million feet.

Fort Frances, Ont.—A large, new woodworking factory is about to commence operation here. The plant will be operated by electric power and will be modern in every respect Messrs. Schroeffer and Johnson are behind the movement.

BUILDING NOTES.

Treherne, Man.—The Municipality of South Norfolk is asking tenders for a municipal building of solid brick, 22 x 36 feet, the cost to be about $2,500.

Edmonton, Alta.—Work has been commenced on a $100,000 banking office here.

Winnipeg, Man.—St. John's College has let to Worsick Brothers the contract for the erection of a new college at a cost of $40,000.

Moose Jaw, Sask.—The Western Building Company have been awarded the contract to build the Edward schools for $30,972.

Toronto, Ont.—The Methodist Book-Room have decided to erect a new ten-storey building on the site of the present book room on West Richmond Street. This will cost in the neighborhood of $200,000.

Winnipeg, Man.—The contract for the bridge at St. Andrews locks has been awarded to the Brown Construction Co., Limited, of Winnipeg. The contract price is approximately $150,000.

Edmonton, Alta.—C. W. Sharp & Son recently signed the contract for the new Canadian Pacific building here to cost $350,000. Work will commence at once.

St. Catharines, Ont.—A six-storey building will be erected by J. Birchenough soon. The price paid for site was $750,000. No details are given.

Quebec City—A new immigration building is now under construction. The building will be 800 feet long by 85 feet wide, of two storeys and reinforced concrete construction. It will cost $350,000. C. E. Deacon & Company, of Montreal, are the contractors.

Victoria, B.C.—The Westholme Lumber Co. is constructing a 7-storey $100,000 block for Hibben-Bone Co., and also the new St. James Hotel.

The Canadian Department of Public Works has advertised for tenders for the construction of the Quebec Dry Dock. Tenders will be received up till July 2nd. The dry dock is to be not less than 1,150 feet in length, 110

feet clear width at entrance, and at least 37 feet in depth over sill and keel blocks. It is to be completed within four years from date of agreement.

Toronto, Ont.—A new hotel will shortly be built on King Street west, to be known as the new Woodbine Hotel. T. H. Herbert is the architect of the building which will cost about $150,000.

Galt, Ont.—Messrs. Thomas and Hancock, of Galt, has secured the contract for the new Bank of Toronto office here. This firm has sublet the contracts for the different trades in connection with the construction of the building.

Vancouver, B. C.—A first-class opera house is about to be started here. Its seating capacity will be about 1,550 and will cost approximately $600,000. The building, which will be five stories high, will be of steel-frame construction.

Saskatoon, Sask.—The Canadian Pacific Railway has purchased fifty feet of land as site for a proposed modernly equipped office building to cost about $200,000.

Moose Jaw, Alta.—It is reported that W. B. Sherman of Calgary, is about to erect a theatre capable of seating 1,200 to cost about $100,000.

Saskatoon, Sask.—A large Winnipeg building firm has purchased a site on 20th street west and will commence at once the building of a seven storey apartment block.

Athabasca Landing, Sask.—What will be the first pulp mill west of Sault Ste. Marie, Ont., is shortly to be built here. Plans are not yet furnished.

Valley Railway, N. B.—The following firms been awarded contracts for the Valley Railway:—James H. Corbett & Sons, from Rothesay to Fredericton, 66 miles; Quebec Contracting Company from Fredericton to Woodstock, 61.5 miles; Kennedy & McDonald, Woodstock to Centreville, 25 miles.

Western Canada.—Among a number of buildings to be erected in Western Canada in the near future are the Winnipeg drill hall to cost $100,000; Calgary post office to cost $200,000, and a warehouse to cost $100,000, also at Calgary, Alta.

Winnipeg, Man.—Plans are in preparation in the office of Ross & McFarlane, architects for a 12 storey office building. The price paid for the property was $3,450 per foot or $172,500 in all.

Port Arthur, Ont.—Within a month it is expected that three storey steel building will be erected to cost $70,000. Messrs. Laird and Peacock of Regina, are behind the venture.

Transcona, Man.—The C. P. R. recently awarded a contract to Barnett & McQueen for a million bushel transfer elevator with all modern appliances. Work will begin at once.

Winnipeg, Man.—A Fort Street property was recently sold to an English syndicate for $100,000 and upon this property a block of offices are to be erected to cost $1,000,000.

RAILROAD ORDERS PLACED.

Montreal, P.Q.—A report states that the management of the Grand Trunk Railway have recently placed freight car orders as follows:—1,000 box cars with the Western Steel Car and Foundry Company, of Chicago; 2,000 box cars with the Canadian Car and Foundry Co., of Montreal; 250 auto cars with the American Car and Foundry Co., of Detroit; 250 auto cars with the Western Steel Car and Foundry Co., of Chicago; 250 refrigerator cars with the Canadian Car and Foundry Co., of Montreal; 1,000 new steel hopper bottom coal cars with the Pressed Steel Car Co., of Pittsburg.

Montreal, P.Q.—A report states that the Canadian Pacific Railway Co. has ordered 250 new engines and 12,500 box cars. It is altogether likely this is the largest amount of rolling stock ever placed on order at one time in this country.

CATALOGUES RECEIVED.

The Railway Asbestos Packing Co., Ltd., Sherbrooke, Que., have sent us a couple of booklets explaining the properties and advantages of the new Asbestos Lubricants lately produced by them. These lubricants are known by the trade names Journolene, Asbestolene and Spedolene. Journolene is especially intended for lubricating the journals of railway cars, street cars, pulp and paper mill machinery, etc. It consists of an amalgamation of asbestos with certain high-grade oils into a lubricating substance that cannot, it is claimed, be disintegrated by wear, and improves with age. It is offered as a decided improvement over wool-waste and oil as a packing for journal boxes, from the viewpoint of both price and efficiency. Asbestolene is intended for the lubrication of all kinds of heavy gearing, while Spedolene is designed for automobile use.

The Fosdick Machine Tool Co., Cincinnati, Ohio, has issued new circulars, showing their 4 ft. and 5 ft. National or simple type Radial Drills. These machines are their latest style, and have all the up-to-date improvements.

Federal Engineering and Supplies, Ltd., Toronto and Montreal, have issued a booklet showing examples of drives where Scandinavia belting can be used to advantage, both for transmission and conveyor purposes. Scandinavia belting is made of best grade long fibre cotton, and after being spun tightly into yarn, is very closely woven. It is then stretched and filled with a bituminous filling to make it as nearly waterproof as possible, and is then rolled between heavy rollers. This process results in a very strong, durable belt of uniform texture.

Darling Bros., Ltd., Montreal, the well known heating specialists, have forwarded a copy of their new book dealing with the Webster vacuum system of steam heating for factories, hotels, offices and public buildings. The book contains 80 pages and treats the subject very fully. Numerous explanatory diagrams are given, together with some excellent half-tones of many important buildings throughout the Dominion that are heated on this system.

The Watson-Stillman Co., New York, have issued their catalogue No. 85, which illustrates and describes the company's patented hydro-pneumatic wheel presses for belt or motor-drive. The hydro-pneumatic action of the ram, combining the certainty of hydraulic power with the quicker action of pneumatic tools, greatly increases the capacity of the machine. Air pressure from the shop system is used.

Another catalogue (No. 83), issued by the same firm, deals with hydraulic benders for rails, channels, tees, etc. These may be hand-operated, belt or motor-driven.

The New Process Twist Drill Co., Taunton, Mass., have brought out a new catalogue and price list of their carbon and high-speed twist drills. These are made by a hot-forging process from round stock. The round bar is forged to the correct profile and then twisted while hot. Clearance is milled on them and they are then sand-blasted and ground to size. The company has been making drills for the past 25 years, and all their work is guaranteed against defects of material and workmanship. A new line now being introduced is the "Reliance" high-speed drill, which is made from profile stock and inserted in a carbon steel shank by a patented process.

Baker Bros., Toledo, Ohio, have favored us with copies of the catalogues Nos. 7B and 10, which set forth the merits of their fine line of drilling, boring and tapping machines, and of their well-known keyseating machines respectively. Parties interested are invited to write for copies.

The Skinner Chuck Co., New Britain, Conn., have just issued their new catalogue and price list for 1912. Two additions have been made to the firm's well-known lines of lathe, drill and planer chucks. These additions consist of an all-steel independent lathe chuck and all-steel face plate jaws. Both lines are intended for the heaviest class of work in railroad shops, government works, etc.

The Scully Steel & Iron Co., Chicago, have mailed us a copy of the Scully "Blue Book" for 1912. This forms the firm's catalogue of Iron, Steel, Machinery, Heavy Hardware, etc., and also contains many valuable reference tables.

William Steele and Sons Co., Toronto, Ont., have forwarded us a copy of a prospectus issued by them dealing with the various merits of Reinforced Concrete and Steel Construction, with special regard to industrial buildings. Several excellent views of completed structures and those in the course of erection are shown.

"Hydraulic Benders" is the title of a new and interesting 64 page 6 in. by 9 in. catalog devoted exclusively to hydraulic machines just published by the Watson-Stillman Co., 50 Church St., New York. Hydraulic benders are now commonly used for bending all kinds of rails, structural shapes, reinforcing rods, and pipe; for shaping automobile frames; for straightening rods or shafts while held between lathe centres, and in almost every other conceivable place where heavy bending is to be done. Free copy will be mailed to interested parties requesting Catalog No. 83.

The Watson-Stillman Co., Hydraulic Engineers, 50 Church St., New York City, have developed a filling liquid for hydraulic tools such as jacks, presses, punches, benders, etc., that does not freeze, thicken, gum or change chemical composition; and is invariably protective to the metal surface and packings with which it comes in contact. This liquid, called Jackohol, is described in a newly issued folder, Bulletin J, which will be sent to anyone interested.

The Ruggles-Coles Engineering Co. have sent us a copy of their catalogue on rotary dryers; also their catalogues on the uses of Monel Metal. This metal takes polish like silver and retains it indefinitely. It is also non-corrosive. Copies will be sent on request to the sole Canadian agent, J. L. Danziger, 704 Eastern Townships Bank Building, Montreal.

The Morse Twist Drill & Machine Co., New Bedford, Mass., have sent us a copy of their 1912 catalogue. It is got up on similar lines to previous catalogues issued by this old established firm, but is more complete; a number of new tools being illustrated.

The Watson-Stillman Company, 50 Church St., New York, has just issued Catalog No. 85 Hydro-Pneumatic Wheel Presses. This catalog describes and lists their line of full hydro-pneumatic wheel presses and those with hydro-pneumatic pull-back only. Seventy-six types and sizes, on which the Watson-Stillman Co. have exclusive patents, are listed. A copy will be sent free upon request.

The John Morrow Screw & Nut Co., Ltd., Ingersoll, Ont., have issued a revised catalogue which illustrates by high-class cuts some of the leading standard and special lines manufactured by this well-known firm. These include standard and special screws of all kinds and special milled work in iron, steel or brass. The company manufactures hollow set screws in large quantities, while the Morrow cold punched nuts are too well known to need more than passing mention. Some interesting views are given of the interiors of the firm's offices and shops at Ingersoll.

The C. A. Dunham Co., Ltd., Toronto, Ont., have forwarded a copy of their latest booklet illustrating the Dunham vacuo-vapor system of steam heating. This is a low pressure two-pipe vacuum system operating automatically without the use of a vacuum pump. The method employed is very simple and is fully explained in the booklet.

The Lumen Bearing Co., Buffalo and Toronto, have favored us with a copy of a booklet recently issued by them to show their facilities for making all kinds of non-ferrous castings and ingots. Excellent views of the Buffalo plant are given, while the whole booklet is attractively gotten up.

The W. S. Rockwell Co., 50 Church St., New York, have issued catalogue No. 14, illustrating various representative installations of Rockwell oil furnaces for annealing, hardening, carbonizing, brass melting, etc., etc.

The Adams Co., Dubuque, Iowa, send us a copy of their circular No. 812, which describes and illustrates the special features of the No. 4 Farwell Universal Gear Hobber. This machine will cut spur, spiral and worm gears, etc., automatically, in all sizes and angles, up to 2 feet in diameter, and can also be used for circular or continuous milling. It is not adapted for cutting bevel or internal gears.

A copy of the pamphlet advertising the Gear Hobbing machine manufactured by the **Reynolds Machine Co., Moline, Ill.**, has been received. The tool is well illustrated by no less than four cuts and its operation is described at some length. A cutter having the form of the teeth required is not used, but a hob having the shape of rack teeth which generates the proper curves on the gear teeth is employed instead. The machine cuts only spur gears.

The Independent Pneumatic Tool Co. of Chicago and New York, have issued a most attractive catalogue of their pneumatic tools. The book is printed on an excellent quality of paper and the cuts are exceptionally good. The various uses to which their wood and metal working tools can be employed are well illustrated. The book cannot but prove interesting and instructive to all those interested in this line of machinery.

The Reynolds Pattern & Machine Co., Moline, Ill., have forwarded us a copy of their catalogue dealing with automatic screw-drivers. These machines are substantially constructed and from the way in which they are received by manufacturers, in both wood and iron working shops, are evidently quite capable of doing all that is claimed for them.

The J. G. Blount Co., Everett, Mass., have forwarded us a copy of their 1912 catalog No. 14 in which their very complete line of grinding, buffing and polishing machinery is very tastefully illustrated. Another line which they manufacture is speed lathes. The various types of these machines are very pleasingly illustrated by a large number of excellent cuts. The splendid quality of their product is briefly but strongly emphasized in the catalog.

BOOK REVIEWS.

Starting currents of transformers, with special reference to transformers with silicon steel cores, by Trygve D. Yensen, has just been issued as Bulletin No. 55 of the Engineering Experiment Station of the University of Illinois. Price, twenty-five cents.

FOR SALE
A Canadian Patent Packingless Globe Valve.
Something new. Best offer takes it.
A. L. KERBAUGH,
1519½ Chen St., Allentown, Pa.

The transformer has come to be regarded as one of the most reliable and simple pieces of electrical apparatus. As new material, however, is utilized to increase its efficiency, new problems arise. One of these problems is the momentary rush of current that occurs upon closing the primary circuit of a transformer. In Bulletin No. 55 it is shown that while this starting current for old type transformers may rise as high as four times full load current, it may rise to more than seven times full load current for the new type with silicon steel cores. The phenomenon is fully explained and illustrated by means of oscillograms.

Tests of Columns. An Investigation of the value of Concrete as Reinforcement for Structural Steel Columns, by Arthur N. Talbot and Arthur R. Lord, has just been issued as Bulletin No. 56 of the Engineering Experiment Station of the University of Illinois. Price, twenty-five cents.

This bulletin gives an account of a series of tests to determine the strength of a structural steel column of considerable strength having a filling of concrete. The tests show that this type of column, if properly made, is a reliable and efficient structural member, and that nearly all the strength of both steel and concrete is developed. The tests also show that up to the point of failure of the column, the fireproofing shell of concrete adheres to the remainder of the column.

MISCELLANEOUS.

Toronto, Ont.—A. J. Halford, Canadian representative of the English Bus Company which intends to operate buses on Toronto's streets, says that his company will erect factories in Toronto to cost for construction and equipment a half-million dollars. The difficulties arising from British labor troubles and shipping delays had led to a realization that to successfully operate buses in the cities of Canada they had to be surer of their supply than they were at the present time, when their buses come from England. It is the intention of the company to run buses, not only in Canada, but in cities of the States, Mexico, and the Central American countries. They will make all of them here, and as the numbers are expected to run up into the thousands yearly, it means a big plant, and the employment of many men. The site for the factory has not been secured yet, but Mr. Halford intimated that he had several properties under consideration.

Hamilton, Ont.—The Steel Castings Syndicate, a new company formed of Buffalo, Brantford, Toronto and Hamilton capital, has decided to locate here. C. W. Sherman, of Buffalo, late of Pratt & Letchworth, will be manager. The capitalization is $300,000.

Byng Inlet, Ont.—The two saw mills of Graces, Bigwood & Co., which burned here recently, were among the finest in Canada, having an output of about 55,000,000 feet per annum. The box factory, power plant (consisting of electric dynamos in a separate building), and the company's stock of lumber were saved. The fire is a serious blow to the town.

Montreal, Que.—If the plans of the Dominion Government do not miscarry, Montreal will soon possess the largest and most magnificent Customs examining warehouse in Canada.

Edmonton, Alta.—The whole of the above-ground plant of the West Coal Company at Clover Bar has been destroyed by fire, which did damage to the extent of from $35,000 to $40,000. The mammoth blaze broke out in the roof of the boiler room at the mine, spreading from that point until the entire buildings at and around the pit head were enveloped in the flames.

Montreal, Que.—Plans have been submitted by Messrs. Marchand and Haskell, architects, for the construction of an annex to the City Hall, ninety-four by one hundred and seventy-six feet, providing for an imposing gray sandstone building, whose cost, according to the lowest tender amongst those opened by the Board of Control, will be $649,000. This tender was made by the Peter Lyall & Sons Company, Limited; the next lowest being that of C. E. Deakin, $678,000, and the highest that of Mr. Joseph Bourque, $725,000.

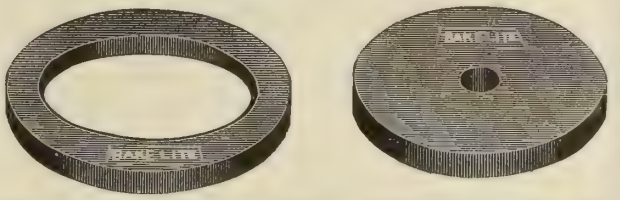
These are the telling points about

Bakelite

Valve Discs



They will not leak under high temperature, excessive pressure or when used in acids or other special liquids. Neither cold water, dry or superheated steam has the least effect upon them. BAKELITE Discs are a gas-tight fit.

BAKELITE is a successful substitute for expensive metal. Its structure is fibrous, giving strength and hardness. It can be reground and refaced, always retaining a uniform surface. It cannot be injured, except by accident or friction.

Remember Bakelite PUMP VALVES do not warm with changes of temperature.

Order your valves fitted with Bakelite Valve Discs and stop that perpetual annoyance and expense caused by leaking valves. Depend upon it, Bakelite Valve Discs will not leak.

WRITE FOR PRICES OR ASK YOUR DEALER.

IT PAYS TO BUY THE BEST

AIR HOIST!

The best may not be the cheapest but IT IS the most economical.

Economy is not effected by low first cost but by eliminating waste—waste of time; waste of power; waste of opportunity to promote production and, principally, waste of money, which is the sum of all other wastes.

You can cut out air hoist waste by installing Rand designs.

You save time because they are convenient and operate accurately.

You save power because the design and workmanship is the best on the market.

You save money because they last a life-time and give the best of service with practically no repairs.

BUY "RAND" HOISTS AND KEEP DOWN YOUR POWER AND REPAIR BILLS.

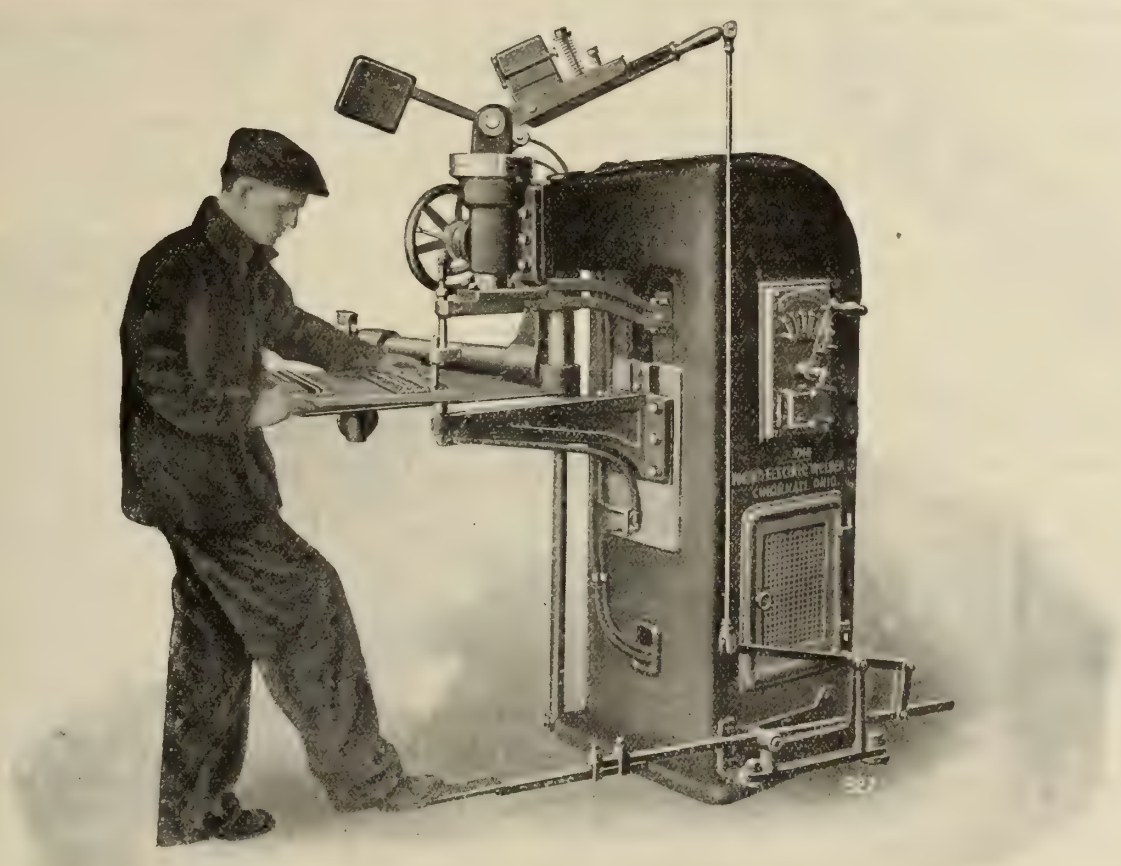
QUICKER THAN RIVETING AND BETTER



No. 150 SPOT WELDER.—With Table and Combination Hand Lever and Foot Treadle.

Welds 1/8 inch to 1/8 inch. Welds 30 ga. to 30 ga.

Last month we showed a cut of this same machine being operated by hand, but it can be operated just as easily by foot, as shown in the above cut. And it takes only 30 seconds to make the change.

Notice how the foot treadle is connected to the lever handle? The treadle is adjustable—can be extended directly under and beyond the centre line of the dies—or it can be swung around to the side to suit the operator's convenience.

The current is turned on and off automatically at the switch.

The ball-bearing adjustable table supporting the work is shown raised level with the dies. By means of the hand wheel it can be dropped to within six inches of the floor. Just the thing for bulky stock. Saves the expense of a helper in handling the work.

But this is not a complete description of this machine with its many advantages. We give that in our new No. 12 Bulletin. We also describe machines of lighter and heavier capacity, but if what you want isn't shown, we'll design it for you.

Let us send you this No. 12 Bulletin anyway. It's full of valuable information regarding electric welding.

Riveting By Electricity

NO PUNCHING REAMING RIVETING

Reduce three operations to one by Electric Welding. Secure greater efficiency and save three-quarters of your present labor charges. **Why** follow old methods, when new ones will make you larger profits. **We** are not limited to one-eighth of an inch in thickness of metal. We can weld heavy material as well as light, and our machines adapted for heavy work will also take care of light work. **Send** us sample or write for particulars.

Truths About Steel Tests

Tests are said to be expensive. But tests are experiments to make improvements. Without such experiments you can make no improvements. Improvements must be made to keep up with your competitors. Therefore you must make tests. But you need not make useless tests.

If you are convinced the steel is new to you and you are reasonably sure of the high standing of the firm selling it; it is not only worth your while to make tests, but you must do it—if you are progressive and have your business instincts alert.

It is not necessary to put too much trust in the results, good or bad, obtained by others. Conditions may be different with them. Make your own tests. Get first-hand information.

You will find Sisco Acorn Steel worth trying.

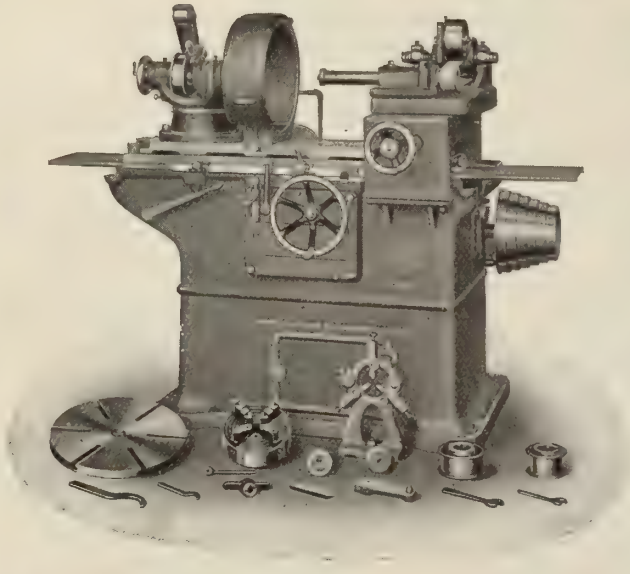
A New Machine For Grinding Straight or Taper Holes In Gears, Cutters, Collets, Bushings, Etc.

No. 22 INTERNAL GRINDING MACHINE



THIS machine meets the requirements of all varieties of internal grinding within its range that can be revolved. Taper holes can be ground as easily as straight ones.

New and interesting features in design, combined with many of the successful constructions of our universal grinding machines, insure accuracy, handiness, rapid operation, and great durability in this latest addition to our line.

The advantages of a machine designed especially for internal grinding are worth investigating. We will gladly send you an interesting circular, on request.

Back

ACTUAL SIZE

First Come—First Served

The Celluloid Disc (illustrated above) shows at a glance the proper speeds and feeds for high speed and carbon steel drills up to 3 ins., tap drill sizes for all U.S. St'd Taps, and the decimal equivalents of all fractional diameters from 1/64 inch to 1 inch, varying by 64ths of an inch.

As our supply of these Handy Indicators is running low. we wish to insure that the remainder of our stock will reach only those who can use them to advantage. Accordingly we have decided to make a nominal charge for them of twenty cents ($0.20) each.

Cut off the coupon and mail it with the stamps, or enclose the stamps in a letter. Orders will be filled strictly according to the date they are received.

No requests will be considered unless they contain the full amount (twenty cents) in postage, but remittances received after the supply is exhausted will be returned.

The CLEVELAND Twist Drill Co.

1250 E. 49th Street CLEVELAND, OHIO

THE CLEVELAND TWIST DRILL CO.
1250 E. 49th St., Cleveland, Ohio.

Gentlemen: I am enclosing 20 cents in stamps for which please send me, postpaid, one of your Celluloid Speed Discs.

BROKEN CASTINGS

REPAIRED

Never allow your plant to be idle waiting for new castings.

Idle plant costs money, send us your work and save it.

We weld any metal or combination of metals. We cut down steel work such as wrecked bridges and buildings.

INQUIRIES SOLICITED.

The Dominion Oxygen Welding and Cutting Co.

21 Queen Street, MONTREAL.

L. Vigoureux, Manager, Phone Main 7192.

OXYGEN

Of guaranteed purity by the Claude's Process. The largest and most up-to-date plant now in operation on this continent.

OXYACETYLENE

AND ALL SYSTEMS OF

WELDING and CUTTING PLANTS

For welding steel, cast iron, copper, brass, lead, aluminum. For cutting steel and wrought iron.

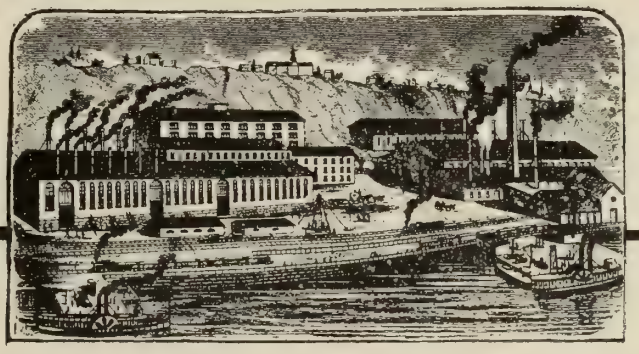
MARINE ENGINES and PUMPS. SHOE MACHINERY A Specialty



BRASS and IRON CASTINGS. BOILERS and REPAIRS.

That we have exceptional facilities at our disposal for the manufacture of all kinds of Machinery —in addition to our business as Brass and Iron Founders, General Contractors and Shoe Machinery Engineers—has been amply proved this year. In the short space of five months, we built and installed all the Engines and Boilers of the new sister steamers "Levis" and "Lauzon," whose trial trips were a complete success. We make a specialty of all kinds of Marine Engine Work, and shall be glad to quote for first-rate products only.

SHOE MACHINERY. Manufacturers of "Non-Royalty" Machines, Metallic and Goodyear, "Fortuna" Skivers, and "Climax" Presses, Sand-papering, Lasting and Loose Studding Machines.

Wire of every description for Slugger and Standard Screw Machines.

The Canadian General & Shoe Machinery Company, Ltd.

ERNEST CARON, Managing Director

STEEL

Sheets and plates - any width up to 50 inches, any thickness up to one inch.

Merchant bars, shafting and heavy forging of all kinds.

PIG IRON FOR FOUNDRY USE.

UNSURPASSED EVAPORATION HIGHEST IN CARBON **COAL** LOWEST IN ASH BEST ALL ROUND STEAM COAL.

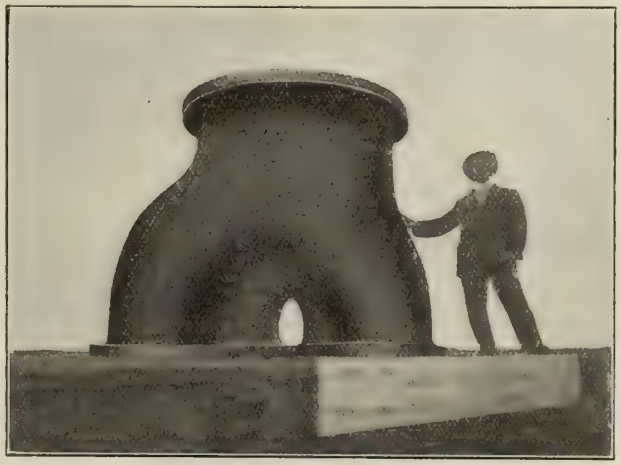
The Nova Scotia Steel & Coal Company LIMITED.

NEW GLASGOW, N.S.

STEEL CASTINGS

Our castings are as perfect and efficient as castings can be, yet they can be procured at a price that will ensure economy.

Let us submit you estimates before placing your next order. Write to-day.



Casting for a 10,500 H.P. Water Wheel.

We make New Process Converter Steel Castings, annealed and unannealed.

We also make Chrome Manganese Nickel Steel Castings.

Made in any size from ¼ lb. to 3000 lbs. and **guaranteed right**.

Main Office: 114-116 Jarvis Street, TORONTO
Factories: Morrow Avenue and C.P.R., TORONTO
Eastern Warehouse: 579 St. Paul Street, MONTREAL

We have been making glutrin — the best core sand binder — for 7 years.

It is to-day a staple article —it would not be if it were not "good goods."

Double Ended Polishing Stand

Two Separate Machines in One, Operating Independently of One Another.

SAVES FLOOR SPACE

DESCRIPTION

Length over all, 5 feet 6 inches.
Height to centre of shaft, 38 inches.
Weight, 375 lbs.
Length from end of spindles to tight collar, 7 inches.
Length of Spindles, 30 inches.
Diameter of Spindles, 1⅜ inches.
Diameter of Spindles for wheel, 1¼ inches.
Tight pulleys, 5¼ inches.
Loose pulleys, 5 inches.
Crucible steel spindles.
Bearings extra long and babbitted with Phoenix babbit metal.
All bearings carefully scraped.
With or without Shifter.
Slight extra changes to meet special requirements without extra charge.
Fitted with Compression Oil Cups.
Pulleys turned inside and out and carefully balanced.
Strong and durable and made for extra hard usage.
A strictly high-grade machine and fully guaranteed in every respect.

PROMPT SHIPMENT GUARANTEED.

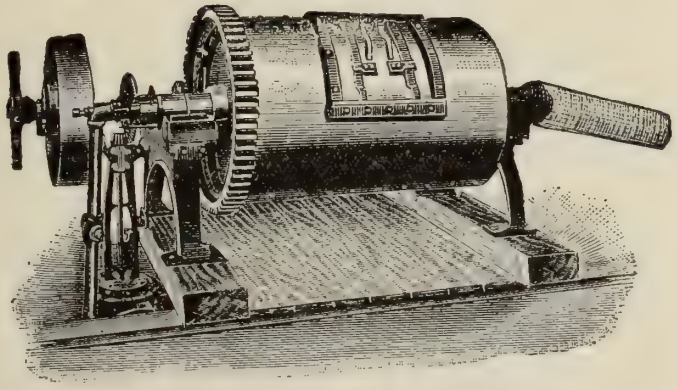
A GOLD MINE

SAVE YOUR IRON



SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

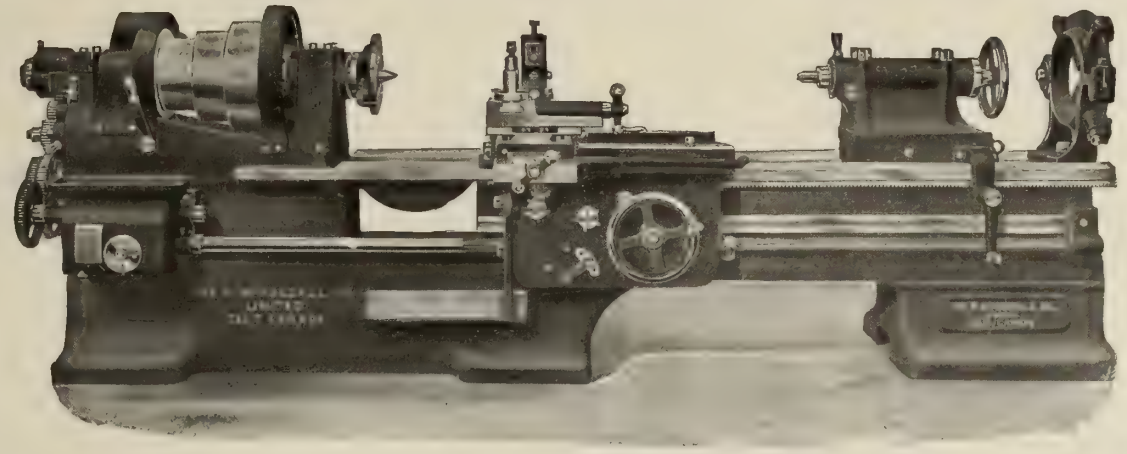
Great Reserve Strength and Capacity in this McDougall Lathe. Read About It. Details Below



NOTE the headstock construction first. See the very wide bearing surfaces and massiveness. The whole machine from head stock to base is like a solid rock. We have done everything that will make this headstock right. It must wear. It must resist strain.

The big bearings are fitted with deep oil chambers and ring oilers. Your lathe is automatically protected against accidental wear and excessive loosening up of the bearings by the operator's omission to oil. Only when you get wear taken care of, have you a headstock which is able to resist strain. Its wide bearings are not only kept automatically in shop perfection, but they take the greatest strain a cutting-tool can give through the work and a spindle in high-carbon steel. The automatic oil device protects the quality of your lathe output by protecting the bearings, so chattering is impossible.

Look at the work of a McDougall Lathe some day. You will see a smooth, clean tool-cut, shining and bright. This shows the even feeding of the work from a firm headstock against a firmly-held tool.

The carriage and apron are non-springing. The action of the tool depends on the solidity of bearing given it by the carriage. This carriage is supported by full "V" bearings, and flat bearings as well. There can be no "lost motion" in the carriage, and none at the cutting edge of the tool.

The tool feed reads to thousandths both ways on the compound rest The automatic feed is of the safety type, so interlocked that your mechanic cannot operate both feeds (screw and rod) at the same time.

Here you have a clean cut from a solidly-held tool working against a solidly-held casting, in a lathe so protected by automatic oiling that it always maintains its accuracy and strength. You can adjust this tool to 1-1000 inch. You cannot break tool or work by accidental operation of both feeds at one time. No breakdowns.

Now look at the tailstock. It has a quick-acting sleeve lock device. This permits quick change of work. In addition the tailstock is secured to the webbed and non-springing bed of the lathe by four bolts with top adjustment. Both kinds of tailstock changes are easy and quick—they save workmen's time.

Take another look at this McDougall Lathe. See how well the gap is supported, and how deep the gap is. Though this is a gap lathe, it is as solid as a standard type, because the base is carried under the entire gap opening. Here you have a gap lathe without a single disadvantage of the gap opening and the deteriorated work it often causes.

Get a McDougall Lathe like this in your factory equipment. Its adjustability, speeds, capacity and practicability make it one of the most perfect machine tools. It is particularly economical where a variety of kinds of lathe work have to be done on a single lathe, because it is a quick-change machine.

Suppose you write us your problem. And to-day, now. The McDougall lathe will raise quality and lower cost.

Make Your Tool Posts by the Pratt & Whitney Method at a Great Reduction in Cost

All previous cumbersome and expensive methods replaced by a new system which produces a tool post far superior in finish, at a fraction of the former cost.

The secret of this system lies in the method of putting in the slots. These are cut in one simple, rapid operation on the recently developed

P. & W. Spline Milling Machine

The order of operations and machines used and recommended by Pratt & Whitney Co. for tool post manufacture is as follows:

1. Cutting up bars of bright cold drawn steel into blanks of a length sufficient for two posts on a Cutting Off Machine.

2. Milling the slots complete without any drilling operation on the

P. & W. Spline Milling Machine

3. Forming lower end of tool post.

4. Beveling the upper ends of tool posts.

5. Drilling and tapping the hole for the tool binder screw on the

P. & W. 2"x26" Turret Lathe

6. Squaring the bottom of the tool slot, which is readily handled on the

P. & W. New Vertical Shaper

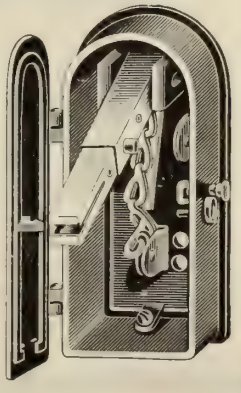
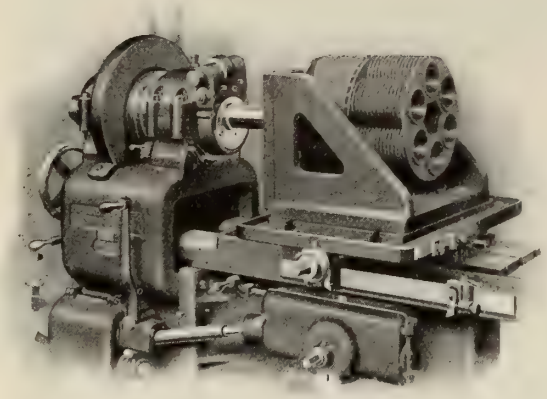
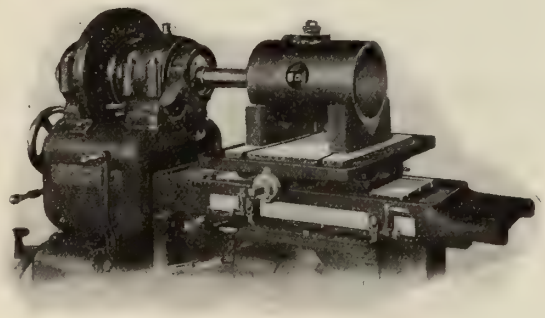
CHICAGO, ILL. - - U.S.A.



All Done On A Heald Cylinder Grinder





The six hole gas engine cylinder at the top with holes 3" in diameter by 12" long and immediately following the plain cylinder with a hole 8" in diameter by 16" long and following this the large gear hole 8" in diameter by 2" long, and also the large hardened tool steel cam, weight 517 lbs., hole 14½" in diameter by 6" long, shown in the lower right hand corner.

These four examples are but an indication of the wide range of usefulness of the Heald cylinder grinding machine as applied in shops all over the world and new uses are being discovered right along in which the Heald cylinder grinder can be employed with a resulting increase in both economy and quality of production. Take that internal finishing job of yours for instance if you are simply smooth boring, reaming or lapping it is quite probable that we have already solved some similar problem and can show you just how to cut costs and improve quality. At any rate, isn't it worth looking into? Just tell us your situation and we will gladly give you our best advice and will place you under no obligation whatever.

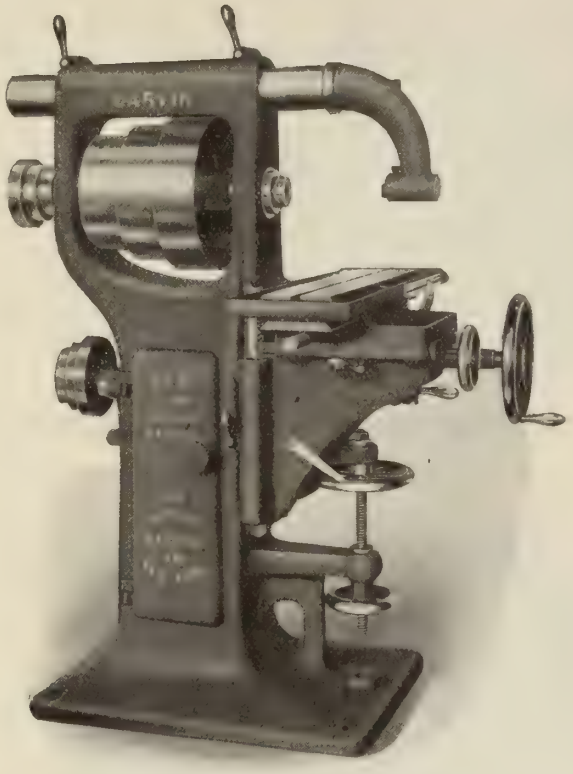
A GARVIN MILLING MACHINE FOR EVERY NEED



No. 21 Plain Milling Machine.
Use Code.....ABSORB.

Fully 80% of the Milling Machines manufactured are used on manufacturing work, and a great majority of this 80% is used on what is called long set-ups. Did it ever occur to you that a simple Milling Machine without frills is made just as accurately as the so-called standard machine, and would effect a great saving in the first cost of your machine tool equipment.

Again, a less expensive operator can be used.

Think this over and investigate the merits of our No. 21 Plain Milling Machine. Made especially for manufacturing work and used by large concerns in gangs of six, to one operator.

Machines are simple and accurate, having lots of power, and enough feed and speed changes to take care of the work they are intended for.

Adjustments—18 x 6 x 13 inches.

Immediate Deliveries

CINCINNATI
418-R

THE combination of the operator and his machine forms a production unit. The efficiency of that unit depends largely upon the handiness of the machine. On most jobs the operating time is longer than the cutting time. The handiness of Cincinnati Millers reduces the operating time. This feature is as important as heavy cutting capacity, That is why we have given it special attention in all our designs and have developed handiness farther than any of our competitors. : : : : :

Canadian Agents—GENERAL SUPPLY CO, Ottawa, Toronto and Winnipeg.

IT IS THE BUILDER'S FAULT

If the life of the tool you are offered is dependent upon the uncertainties of squirt-can lubrication. In buying it YOU assume the risk.

Did you ever count the oil holes on the ordinary machine tool?

We doubt it.

We also doubt if even the operator himself always finds every one of the holes in the morning when he "oils up for the day."

And the **gears** go dry!

Flooded Lubrication is one reason for the success of the VERTICAL TURRET LATHE. Gears, as well as bearings, including table spindle, are constantly immersed in oil, and the proper level is easily maintained—the prominently located sight gauges indicating, at a glance, when the proper supply has been depleted.

Reducing the number of places requiring attention, and making those few prominent, increases the assurance that **proper** attention will be given to all, and, while insuring against loss of time resulting from burned out bearings, **adds** to the productive time of the machine and operator the time usually taken in manipulating the undependable and wasteful squirt-can.

What Is Your Method of Grinding Thread Chasers ?

You know that it is practically impossible to keep threading tools in shape or to regrind them satisfactorily by hand.

The Geometric Chaser or Die Grinder

touches up all Chasers of a set uniformly and keeps them in condition for accurate work.

The machine is adapted for grinding any make of thread Chaser, whether of a stock or special type, and is also equipped with a second grinding wheel for ordinary tool grinding.

In shops where much screw cutting is done, one of these machines will save its first cost in a short time in labor alone, and Chasers that are kept properly ground will last a great deal longer and do far better work than Chasers that are subjected to the hit-or-miss hand grinding.

Let us send you our Special Booklet describing this Chaser Grinder.

The Geometric Tool Company, New Haven, Conn.

High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

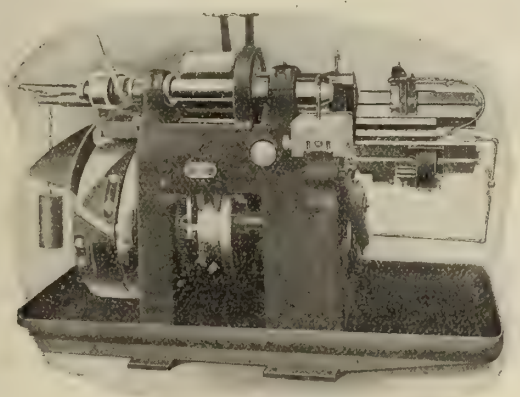
The Gridley Automatic
TURRET LATHE

The Great Convenience

of this Turret Lathe enables one operator to attend to several machines at once. He can use tools tandem when rapid production is necessary. This saves much labor.



"GRIDLEY" SINGLE SPINDLE

Ensures a Smooth, Clean Cut from Start to Finish

This Lathe will be the means of increasing your output, and will handle work of greater length and of more complex character than any other machine of this type.

It will pay you to write for our catalog, which points out clearly the advantages of using this machine.

We manufacture both "Single" and "Multiple" Spindle Automatics.

Hoffman Steel Balls

(Manufactured in England)

are made of the very finest high carbon chrome steel, and are all guaranteed to be perfect spheres, correct to standard size within one ten-thousandth of an inch. The surfaces are glass-hard, with a very high elastic limit, while the interiors are softer, though considerably toughened.

Hoffman Standard Journal Bearings

consist of two hardened rings of finest steel, with curved ball races and a single row of balls in a floating cage of drawn gunmetal—the best anti-friction metal for this purpose. Also made full of balls when required, though we do not recommend this.

Hoffman Standard Thrust Bearings

are made both single and double, on the same lines as the journal bearings, and in exhaustive tests, under a great variety of conditions, they have proved thoroughly efficient and reliable.

Hoffmann Ball Bearings have successfully carried loads up to 500,000 lbs., at speeds of from 1 to 30,000 revolutions per minute. For further information write

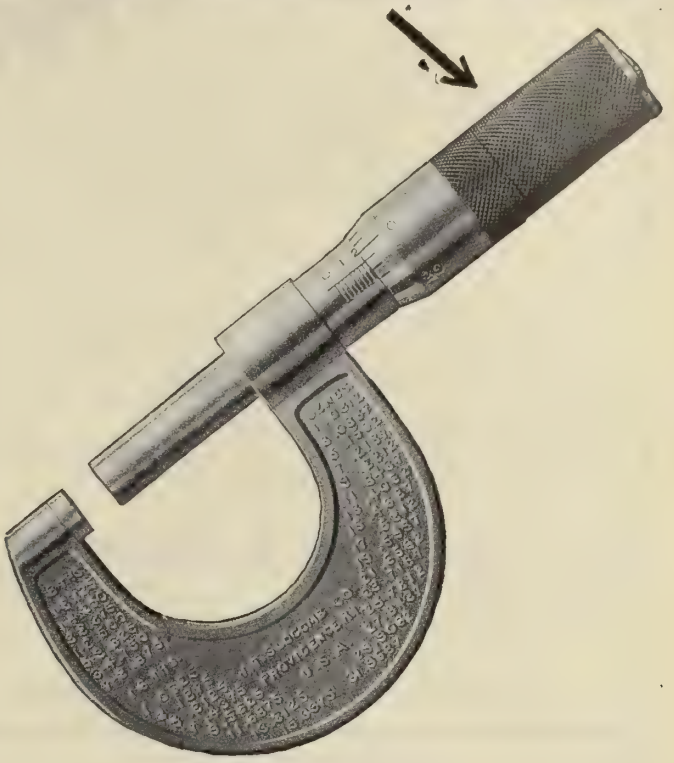
SLOCOMB MICROMETER No. 26 with FRICTION THIMBLE



Think this over

Have you ever known a fellow workman who owned a Slocomb Micrometer who wasn't proud of it? He knows that the adjustments in a Slocomb are worth something to him. It isn't a case of guess and try, it is a certainty. Then, too, he realizes that with the .270 diameter on the screw and anvil, the long thread for the screw to run in, the replaceable thread in frame, the absence of split shanks which attract dirt and wears the thread on the screw, the spring giving the thimble uniform friction, and the other features found exclusively in Slocomb Micrometers are worth while.

He realizes that these things mean a saving of money for him.

You can get the same benefits, for these features are in all Slocomb Micrometers, and every tool is guaranteed to be correct.

If you aren't now using Slocomb tools it will be worth your while to try some.

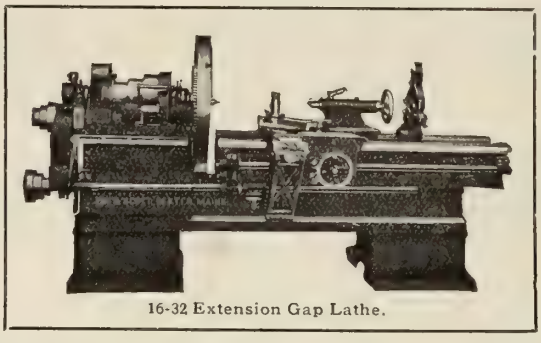
Gem Manufacturing Company
3257 Spruce Street
Pittsburg, Pa. U. S. A.



16-32 Extension Gap Lathe.

How many times have you been compelled to refuse a job—how many times have you had to send out a large piece of work—because your large lathe wasn't large enough?

A twenty per cent. greater investment would have purchased for you, an extra lathe—a large lathe—together with a small one, a lathe with great swing and powerful driving gears, a lathe with the maximum centre distance and the minimum floor space.

When you buy another lathe, think this over—the Fay & Scott extension bed gap lathe is a convenient and easily operated small lathe with a large hollow spindle, a heavy, powerfully triple-geared large lathe, sold at a nominal price, ranging from thirty to fifty per cent. less than a standard lathe of the same size.

Built in eight sizes—14"-28", 16"-32", 18"-36", 20"-42", 24"-46", 28"-52", 32"-56", 38"-66"; any length bed.

Defective Castings Made Perfect

Blow holes, sand holes, porous or spongy spots in iron or steel castings can be easily quickly, cheaply, and permanently repaired with J-M Ferro Compound. It metalizes and becomes a permanent part of the casting.

J-M Ferro Compound

can be finished with a fine file or an emery wheel when hard, and cannot be told from the iron itself, as it has the same color.

J-M Ferro Compound comes in powdered form and is used by mixing to the consistency of stiff putty and applying with a metal or hard wood paddle, a trowel, or by hand.

DIAMOND
High Speed Drills

Will put your factory drilling department on an ECONOMY BASIS that will soon show on YOUR COST SHEETS.

The Consumer of drills naturally has his factory difficulties to solve. He must select those drills that will accomplish QUALITY RESULTS for his products, at a cost that will give him a profit.

We have made **CAREFUL SCIENTIFIC** and **MECHANICAL STUDY** of these problems. Consequently, we can tell you wherein your trouble may be overcome by using the right kind of drills of the correct temper and character of steel.

We make drills for all classes of work. HERE IS WHERE WE CAN MEET ON A PROFITABLE BASIS. Suppose you write us about those conditions and difficulties. **WE WILL ADVISE** you as would your Physician, your Attorney or your Banker, and place at your command the fund of results accumulated for years in our scientific testing department.

WE HAVE BATTLED with your problems for many years and Solved Them. You may be assured our advice will save you money. If the drills you are now using have that "W & B DIAMOND" TRADE MARK ON THE SHANK, YOU ARE RIGHT.

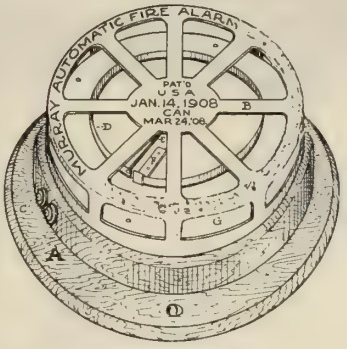
The Murray Automatic Fire Alarm



" Cheaper to have and never need, than to need *once* and not have."

Is a watchman that is always on duty and never goes to sleep.

Here's what a fire chief in one large manufacturing plant thinks of it:

The Murray Automatic Fire Alarm Co.
Toronto, Canada.

Dear Sirs:—

I have practically and thoroughly tested your Automatic Fire Alarm in every way pertaining to its use in factories and public buildings, and find it admirably adapted to the purpose for which it is intended, in effectively sounding the alarm.

Its simplicity and efficiency should at once commend it and secure its adoption and general use by those interested in automatic fire alarms.

JAS. CORBETT,
Fire Chief, Massey-Harris Co., Toronto.

The installation of this system is as simple as that of wiring ordinary call bells. Under the action of heat, when a predetermined maximum of temperature is exceeded, an electric circuit is closed and alarms given by the use of electric bells.

Write us for circular, and give us the chance to quote you price for your requirements.

Seven Great Money-Saving Packings

Engineers and machinists throughout the Dominion are saving thousands of dollars in ***time alone*** by using Goodyear Packings—***short-cuts*** to ***RESULTS.***

Installed quickest and most easily. ***Outlast*** all others. Recognized by all who ***know packings*** as the highest standard of excellence. Use one of these great

GOODYEAR Packings

MAGNET SHEET PACKING

Meets *every requirement*—Boiler Room or Machine Shop. Made of special compound that *resists heat*, hence the *only* packing thoroughly adapted for high pressure uses. Makes tight joint under air or hot or cold water pressure. *Unaffected* by oil, liquor, ammonia or alkali. Retains elasticity.

MAGNET GASKET TUBING

For high pressure. Like Magnet Sheet Packing, this tubing is unaffected by heat, makes tight joint, can't *blow out*. Cut any length to fit any size manhole, hand-hole, plate or pipe flange. Put up in convenient boxes with rubber core and tape.

ROUND DUCK PACKING

Fine quality cotton duck with round core. Used like Hydraulic Packing, *only for lower pressure.*

HYDRAULIC PACKING

Best packing for pump cylinders, inside-packed plungers pumping hot or cold water, and hydraulic elevators. Unexcelled for boiling water and high pressure hydraulic work

CLOTH INSERTION PACKING

For cold and warm water pipes. Unexcelled in pliability, smoothness of finish and strength of cloth insertion. Made of heavier fabric than any other similar packing on the market.

SQUARE DUCK PACKING

Good quality cotton duck and friction to stand cold water. Cut accurately into squares.

SQUARE DUCK WITH RUBBER BACK

Specially adapted for elevator use. Made of superior cotton duck, gum back. Makes packing tight, practically no friction. Gives many times service of other packings of same nature.

VALVES

Unaffected by oil. Used in hundreds of industrial plants. Specially made to meet specific conditions.

Goodyear Packing, Belting, Hose and other rubber sundries enable you to capitalize the brains and experience of the world's greatest rubber goods experts—the knowledge and skill that underlies our reputation as well as that of the Goodyear Tire & Rubber Company, Akron, Ohio, the best known plant of its kind in the United States.

Our Sales of the last four months 50 per cent. greater than those of last year. Defective goods returned only $23.93.

GRIT

The special fitness and value of Magnolia Metal for bearings which are subject to **grit and dust** has always been most noticeable and is frequently commented upon by Engineers as shown in the following letters:

THE CLEVELAND TRINIDAD PAVING CO.
Cleveland, O.

Branch Johnson City, Tenn., Dec. 15th, 1911.

Gentlemen:—We have used "Magnolia" exclusively the past three years on the asphalt plants of this Company that have been in my charge in Oklahoma City, Muskogee, MacAlester, Emporia, Kansas and Johnson City, Tenn.

Have used it on Westinghouse, High Speed and other Engines, also on bearings that were subjected to much **sand and grit,** and find it the nearest to "perfect" of any antifriction Metal.

Very truly,
CHAS. R. COOPER, Plant Supt.,
The Cleveland Trinidad Paving Co.

HOWARD TRUMBO, CONTRACTOR,

Key West, Fla., Nov. 23rd, 1910.

Dear Sirs:—I have used MAGNOLIA METAL for the past 15 years and found it satisfactory in every respect. Used it in thrust bearing, crank and cross-head bearing of the Steamer Bolivar; for the Union Bridge Co., and was on steamer for 18 months; when I left every bearing was O.K., and used it on several other steamers and tugs, also stationary work, and it gave perfect satisfaction. The last time I used Magnolia Metal was on the Hydraulic dredge Minikee, on the pump bearing, especially the bearing next to the pump where **sand and grit** from the pump gets in, a stream of water is pumped next to bearing to keep **sand and grit** out or away from said bearing, and after 8 months' work, this bearing was found in first-class condition, and started on another job last March, and it was still running when I left to take my present position with the Government, Quart. Master Dept., Key West, West Barracks, Fla.

Yours truly,
ALBERT DI NEGRO,
Chief Engineer Ocean Steamer.

GOGEBIC HOTEL AND COTTAGES,

Gogebic, Mich., Dec. 12th, 1910.

Gentlemen:—Having used MAGNOLIA METAL in my business as Marine Engineer for a number of years, I must say it is the best composite metal that I know of for Engine bearings, and has always proved of great value in keeping cool when propeller and crank shafts are run at high speeds, and also when bilge water has washed **grit and ashes** into main bearings during a storm. We use no other metal for bearings that have to be relined.

Yours very truly,
J. E. MARSHALL, Engineer.

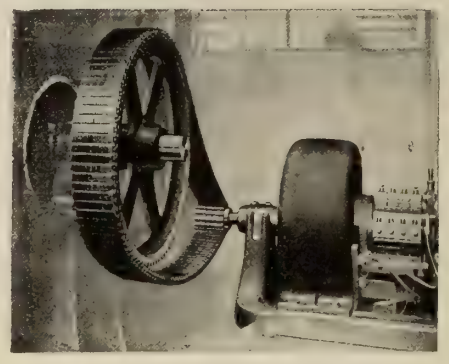
NO machine can turn out full production on less than full power.



50 H.P. Morse Chain Driving Fan.

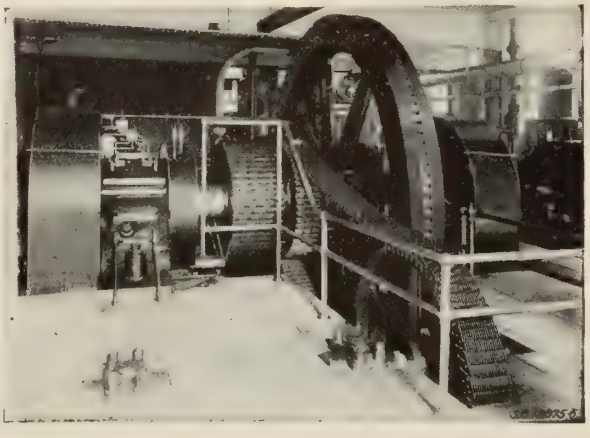
To get maximum shop production, you must use a transmission system which gets most power to your machines.

Morse Silent "Rocker-Joint" Chains

provide the most efficient method of transmitting power. Their loss has been proven under all conditions of service to be not over 1 per cent.

Size makes no difference. Morse Silent Chains transmit 1000, 2000 or 3000 horsepower with the same efficiency as 10, 20 or 30 horsepower.

The two-pin "rocker-joint," an exclusive feature of the Morse Chain, practically eliminates turning and rubbing friction from the joint, Thus, wear is minimized, repair costs cut to almost nothing and maintenance and attendance reduced to hitherto unbelievable amounts



1000 and 500 H.P. Morse Chains Driving Line Shafts.

"SINGLE CONQUEROR"
for Chisels, Cold Sets, Mining and general use.

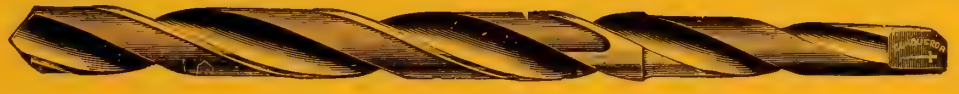
"DOUBLE CONQUEROR"
suitable for Punches, Taps, Dies, Snaps, Shear Blades, etc.

"CONQUEROR"
High Speed Steels in Rounds, Squares, Flats; also Profile Sections.

We claim our Tool Steels are fully equal to any on the market, and that they give better results than many other brands. Our prices are certain to appeal to you.

Before ordering a new supply, investigate the "Conqueror" Brand.

CONQUEROR IMPROVED HIGH SPEED DRILLS



are made from Fluted Profile Section of High Speed Steel. **They are tougher and not so easily broken as the regular milled High Speed Drills, retain a firm edge and are much cheaper.** Made by twisting the rolled bar—no expensive milling—no waste of costly material. Will fit any ordinary Morse Sockets. **There is no Drill on the market that can compare with them in quality or price.**

Get fuller particulars and prices at once.

Save 50 to 75% on Your Tool Costs

By Making Your Own Drills from "CONQUEROR" BRAND Profile Sections

No Forging Required

Easily Ground

Although our profiles naturally run somewhat higher in price than the corresponding sizes of solid steel, on account of the saving in weight, they actually cost less, and produce a tool of such superior excellence that its quality is not even approached by the best of Milled Drills at a lower cost.

These High Speed Profiles are rolled from the Highest Quality of High Speed Steel, the Drill Section being twisted hot, and by their use the mechanic can not only save 30% to 50% of the material from going to waste, but will save the cost of Milling. wear and tear of machinery, and other expenses incidental to tool making.

When buying these Profiles you get **best possible value for your money.**

Write for Particulars.

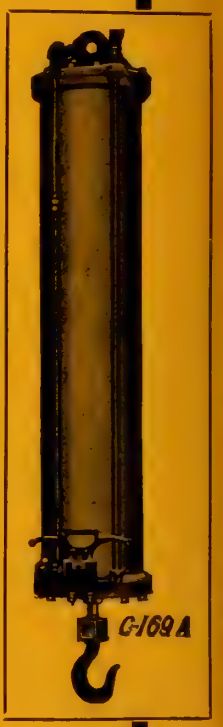
28 LIFTS for 1 CENT

With an INGERSOLL-RAND air hoist you can raise one ton five feet, 28 times, for one cent. Isn't 28 lifts for one cent pretty cheap hoisting? INGERSOLL-RAND Straight Lift air hoists eliminate all rotating mechanism, gears, bearings, etc. The load is simply lifted straight up—no friction, no complicated parts. The lift can be regulated for any speed, and is easily controlled for distance. With this air-balanced hoist the load is easily adjusted a fraction of an inch. This makes them especially adapted to drawing patterns, feeding machine tools, handling structural members, etc.

A special device is provided for holding the load in any position so that the hose may be disconnected and the hoist (and load) run to another point and the load lowered. This is a great convenience in shipping or transferring material.



An Example: To raise a weight of one ton requires an air hoist 6 in. in diameter, supplied with compressed air at 80 lbs. per square inch pressure. To lift one ton 5 ft. with this hoist requires 7 cu. ft. of free air compressed to 80 lbs. pressure. The cost of compressed air at 80 lbs. or 100 lbs. pressure may range from 2 cents to 5 cents for 1,000 cu. ft. free air. Taking the highest of these gives 200 cu. ft. of free air for one cent. This would raise the one ton weight 5 ft. high 28 times. 28 lifts for one cent is cheap hoisting. If the air hoist saves only 6 seconds of a man's time each lift, it will soon pay for itself.

DISTINCTIVE FEATURES

TYPE.—The hoist is of the direct lift air-balanced type, the lower part of the cylinder is connected direct to supply pressure, while air is admitted to the upper part of the cylinder or exhausted from it to lower or raise the load. The hoist draws in no air from outside, so that it may be used in a dusty place if desired.

CONTROLLING VALVE.—Valve is of the hydraulic poppet type, opened by cam lever, closed by spring and held tight by air pressure. The valve is self closing. The opening is gradual, so that the load may be raised or lowered the fraction of an inch at a time. Separate adjustments are provided for limiting the maximum speed of raising and lowering. Valves have brass seats and soft rubber discs, which may be readily renewed. A wrought iron guard is provided around valve.

PISTON. The piston is of cast iron with follower plate to hold the cup-leather packing in place. The piston rod is of steel, turned and polished.

PACKING. Both piston and piston rod are packed with cup-leather packing, which adjusts itself automatically to suit the air pressure and keep tight with the minimum of friction.

HOOK.—Hook is of the swivelling type, in order to automatically adjust itself to the load without straining the rod.

LUBRICATION.—An oil plug is provided in the upper head for supplying oil to the piston and rod. The design of the valve is such that it does not require lubrication.

IN GENERAL.—The hoist is characterized by simplicity of design, accessibility, tightness of valve connections and packing, safety against accident and accurate control of hoisting and lowering.

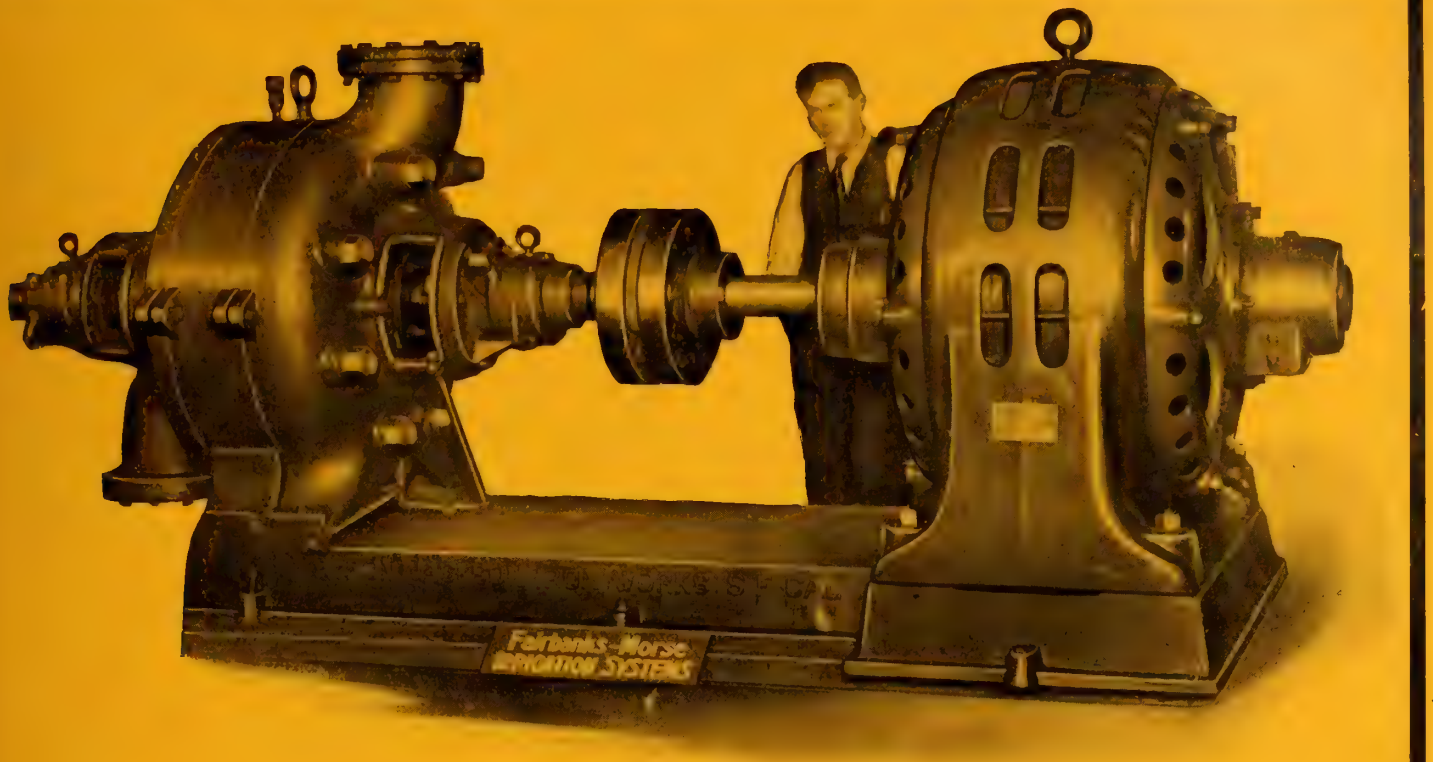
Supply House In Canada



The Largest Direct Connected Centrifugal Pumping Unit in British Columbia

The Vancouver Power Company have recently installed at their works at Coquitlam Dam, B.C., the largest direct connected centrifugal pumping unit in British Columbia. This outfit is to operate in parallel with a number of other pumps that are to furnish water under pressure for sluicing into place the material for their new dam.

This pump is a 10-inch, class "F," two-stage centrifugal, with bronze impellers and renewable bronze diffusion vanes. It has a normal capacity of 1833 imperial gallons per minute when operating at 1160 r.p.m. against a total head of 355 feet or an equivalent pressure of 154 lbs. per square inch. It is mounted on a common sub-base with a 300 h.p. type "B," Fairbanks-Morse squirrel cage, induction motor, 2200 volts, 60-cycle, 3-phase, 1160 r.p.m. at full load being direct connected thereto by means of a flexible leather link coupling.

The motor possesses a feature in rotor construction that is unique. The end rings are welded on to the rotor bars by a new process, making a perfect joint, free from the troubles common to the purely mechanical or riveted joint, such as oxidation, working loose, and solder-throwing. This improvement marks a long step forward in the elimination of rotor trouble.

Our Vancouver Branch supplied and assembled this complete pumping unit. We are in a position to quote on the necessary equipment for any pumping requirements on receipt of specifications.

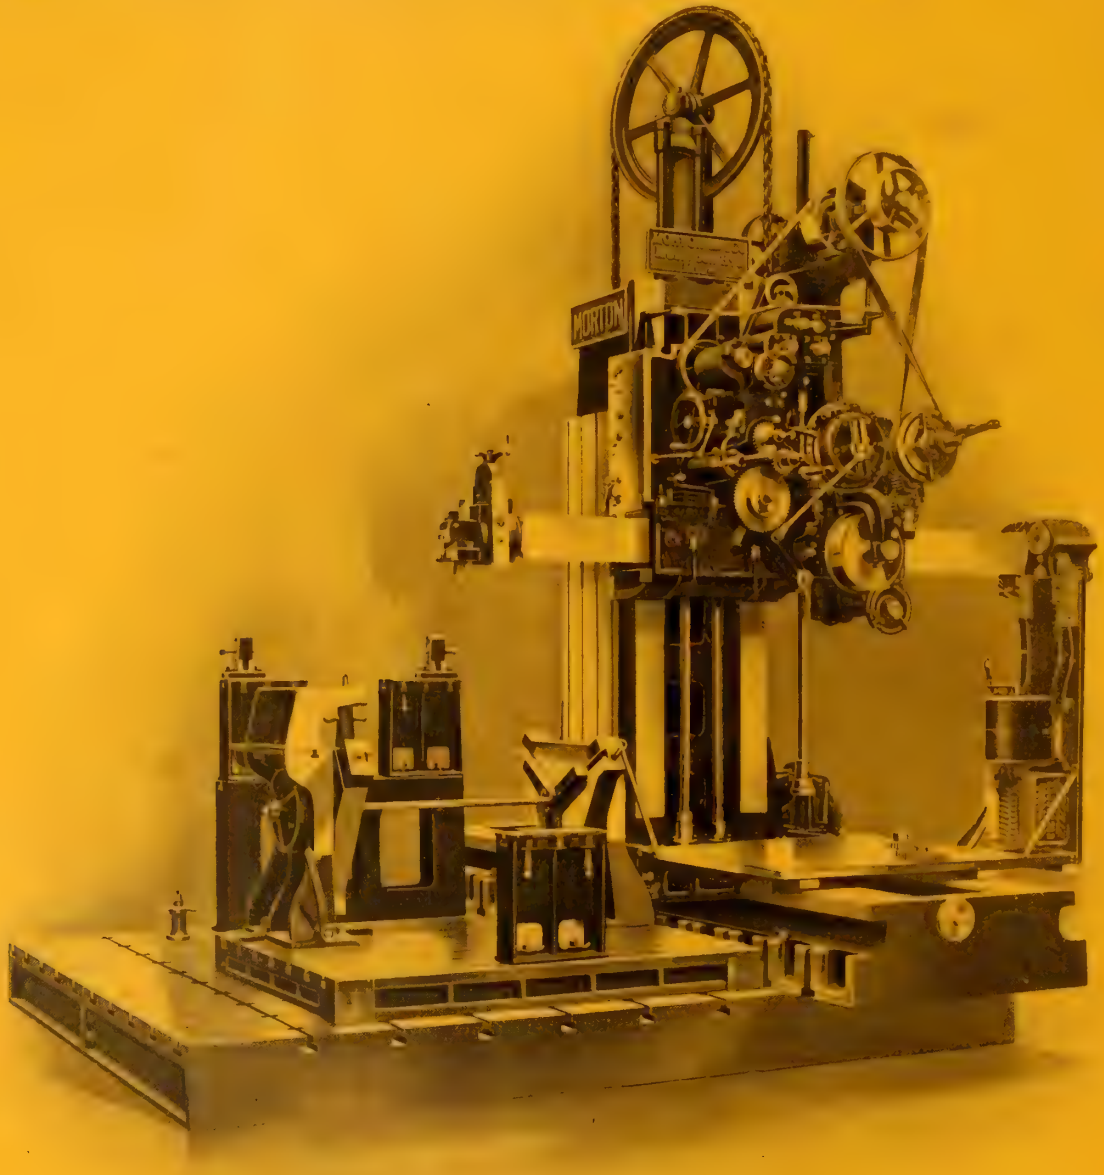
The Morton Travelling Head Draw-Cut Cylinder Planer,

With Equipment. Is a most interesting Machine for the Railroad Shop

BECAUSE

IT REQUIRES one-half the FLOOR SPACE of a HOUSED PLANER. IT REQUIRES one-fourth the POWER. IT WILL PLANE a CYLINDER and MILL the PORTS at one setting in the CHUCKS. IT WILL BORE a PISTON VALVE CHAMBER at the same setting as PLANING. IT WILL PLANE the SMOKE BOX FIT after CYLINDERS are bolted together. It can be operated PROFITABLY on smaller work as it only requires little power. It will plane Cylinders and do a great variety of other work at a saving of 25 to 40%. Many other reasons why.



PRACTICAL—MODERN—EFFICIENT—PRODUCTIVE.

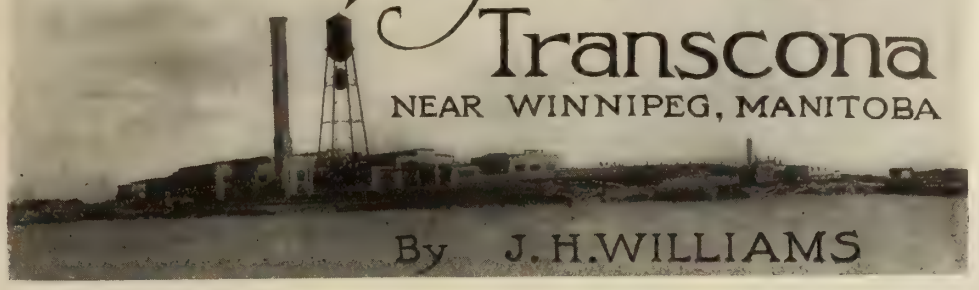
New Shops of the N.T.R. Transcona

NEAR WINNIPEG, MANITOBA

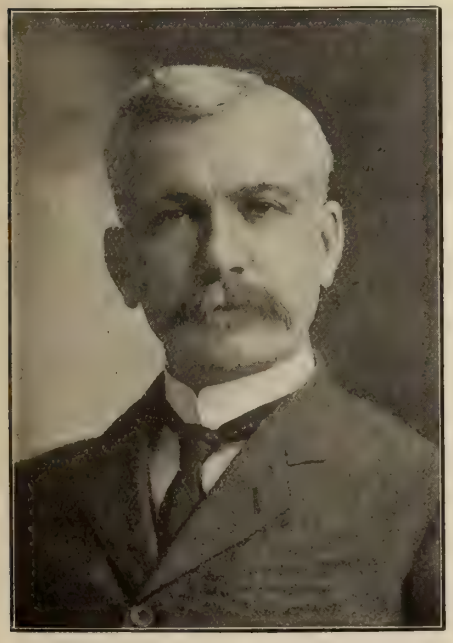


By J. H. WILLIAMS

INTRODUCTORY AND PERSONAL.

THERE was published in Canadian Machinery for November, 1910, a preliminary account of the National Transcontinental Railway shops being built at Transcona, near Winnipeg, Man., with illustrations of the various buildings as they then appeared. Needless to say, great progress has been made since that time. with the result that the shops of the motive power department, together with the power house, are now ready for operation. These are herewith described. Some little time will necessarily elapse before the car shops are sufficiently advanced to permit of their complete description. In conjunction with the shops about to be built at Quebec, the Transcona plant is intended to handle repairs to all rolling stock from Winnipeg to the Atlantic, or rather to Moncton, N. B., which is technically the Eastern terminus of the line. The shops, of course, together with the track of the N. T. R., are to be leased to the Grand Trunk Pacific Railway, who will doubtless also use them for repairs to their Western lines rolling stock, until such time as the pressure of traffic renders necessary the building of other shops further West.

MAJOR R. W. LEONARD,
National Transcontinental Railway Commissioner.



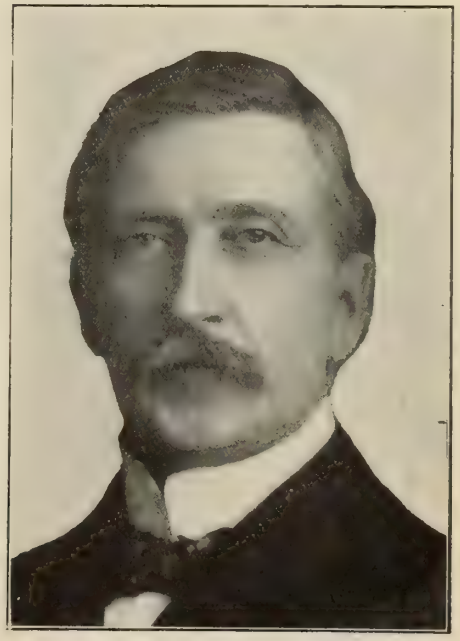
HON. GEO. P. GRAHAM,
Dominion Minister of Railways and Canals—"Laurier" Cabinet.

E. J. Chamberlin, President, G. T. P.

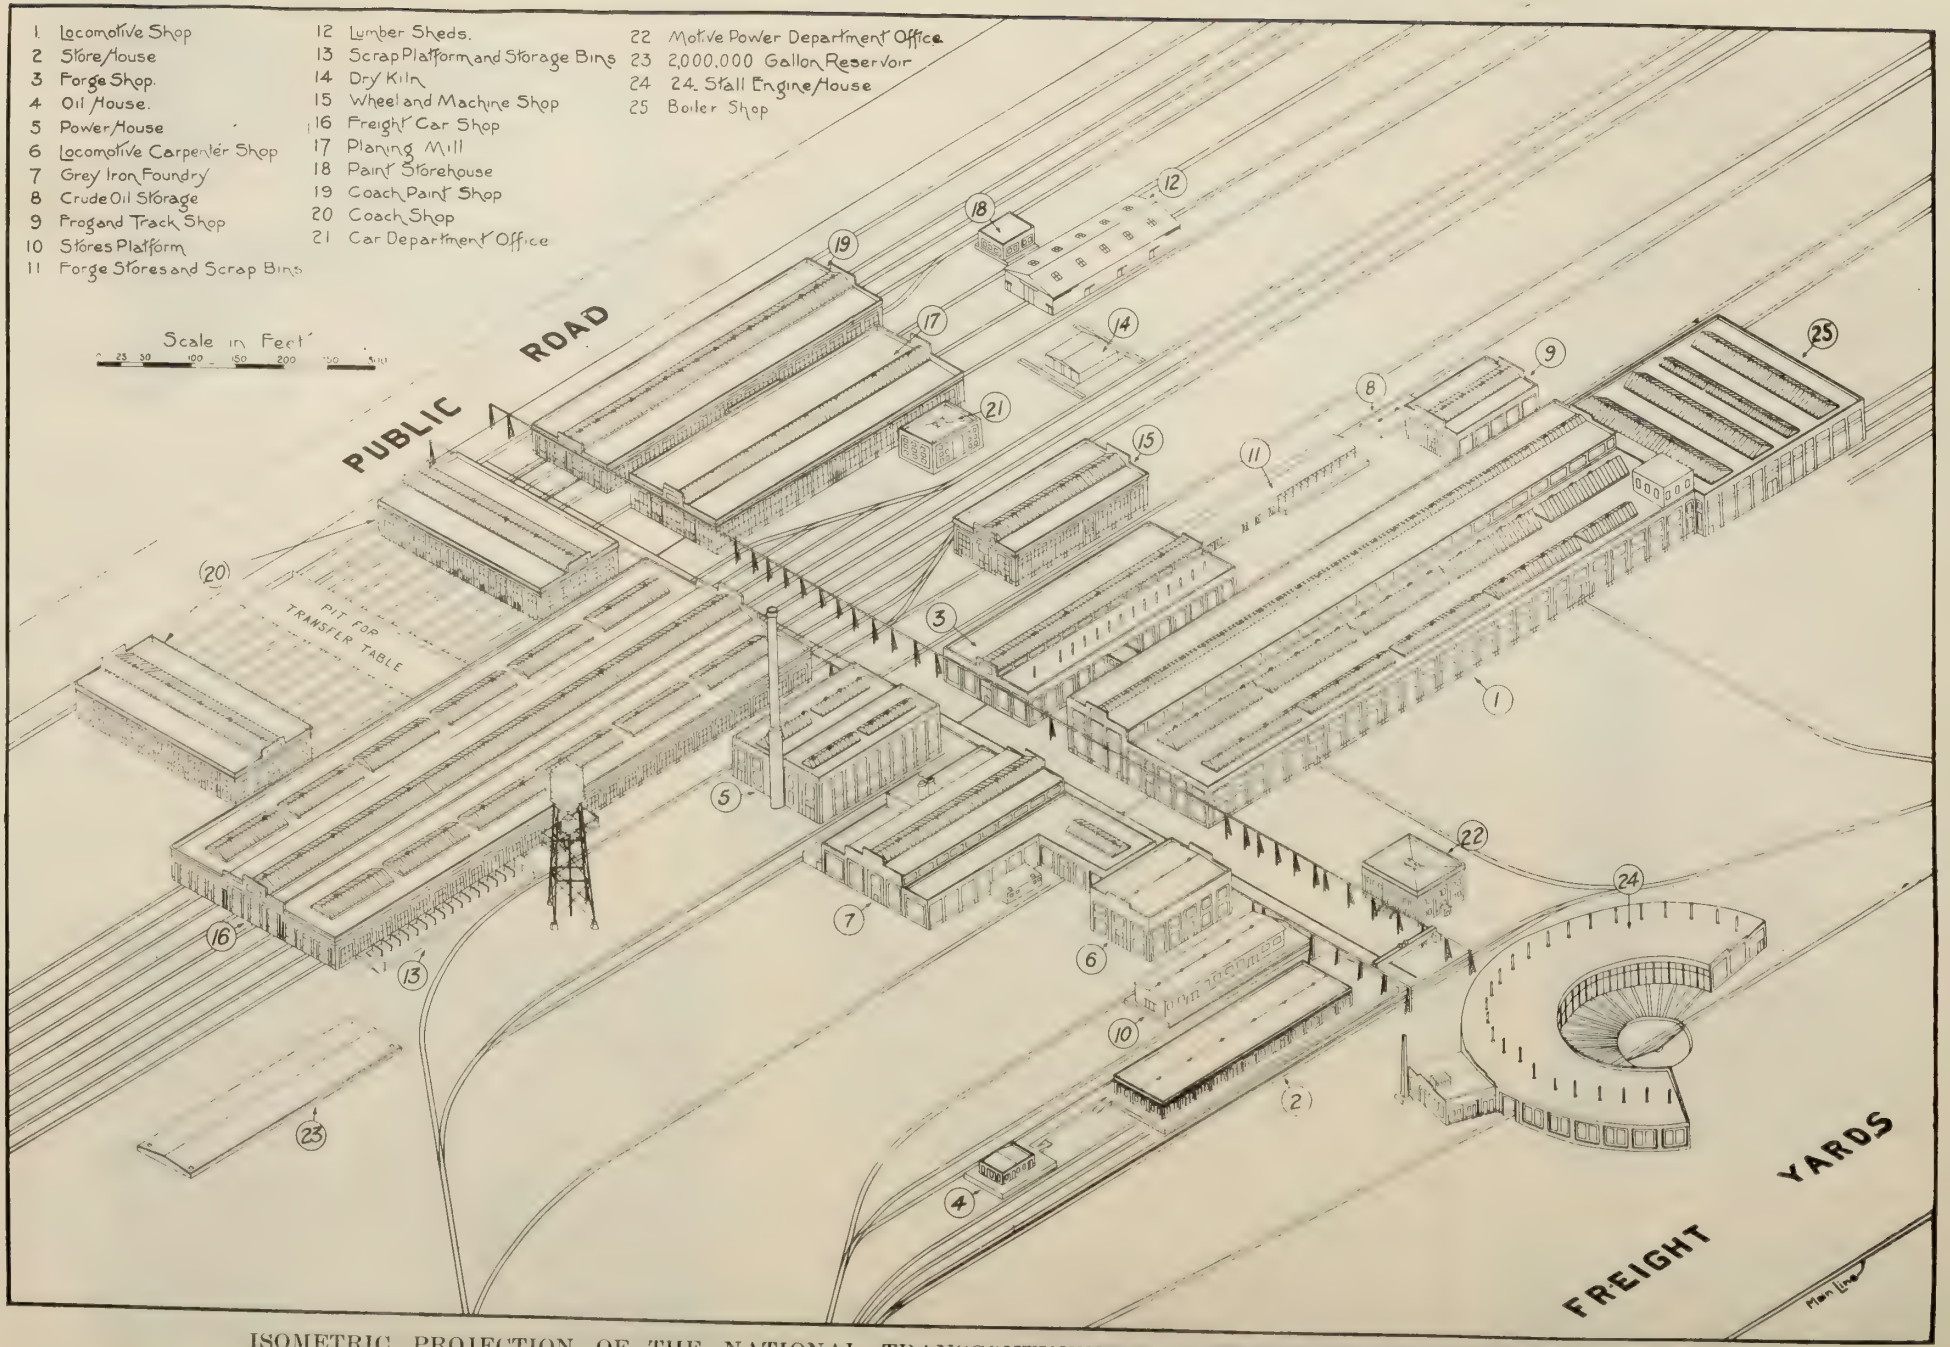
The new president of the Grand Trunk Pacific Railway, Mr. E. J. Chamberlin, whose portrait appears on page 189, is understood to be well satisfied with the shops and equipment at Transcona, and as a railroad man of forty years' experience, he is no mean judge in such matters. Mr. Chamberlin, who is a native of Lancaster, N. H., was educated at Montpelier Methodist Seminary. He began railroading in 1871, and in 1884 became superintendent of the Ogdensburg and Lake Champlain Railway. He was general manager of the Canada Atlantic Railway from 1886-1905, when, on its absorption by the G. T. R., he went to Mexico to supervise some large railway contracts. For four years he was president of the Morelia & Tascambra Railway; afterwards returning to Canada to take charge of the construction of the Grand Trunk Pacific Railway, of which he was made vice-president and general manager. His ability as a railway builder was demonstrated when he performed the construction work on the Canada Atlantic at a very low cost.

W. J. Press, Mechanical Engineer.

The details of the locomotive shops were partly worked out by F. W. Walker, M.E., who held the position of Superintendent of Terminal Shops, N. T. R., until July 1, 1911, when he resigned. On May 23, 1910, W. J. Press, M. E., was appointed mechanical engineer and machinery expert, with headquarters at Ottawa; since which time he has had charge of the completion of the locomotive shops, the construction of the car shops, and has also been responsible for the selection and instalment of all



HON. FRANK COCHRANE,
Dominion Minister of Railways and Canals—"Borden" Cabinet.



ISOMETRIC PROJECTION OF THE NATIONAL TRANSCONTINENTAL RAILWAY SHOPS, TRANSCONA, MAN.

the mechanical equipment, not only in the shops, but along the whole line of the N. T. R.

Mr. Press has been engaged in railway work all his life. He served a seven years' apprenticeship with the South Australian Government Railways, and remained in that service twelve years, having charge of all contracts in connection with the car department, etc.

THE LATE C. M. HAYS.
Former President the Grand Trunk Pacific Railway.

At the outbreak of the Boer War, he was requisitioned for South Africa, and on arrival at Pretoria was attached to the Royal Engineers, under Sir Percy Girouard, who placed him in charge of the Imperial Military Railways' principal locomotive and carriage shops at Pretoria. During this period, Mr. Press constructed a number of the armoured trains which proved of so much service. In the course of the war, nearly one hundred locomotives, blown up by the Boers, were repaired in these shops, and much ingenuity had to be exercised in carrying out the repairs, owing to the lack of material and spare parts. In addition to the usual locomotive and car work, a great deal was done in the way of repairing ordnance, gun carriages, etc.

On the conclusion of hostilities, Mr. Press was appointed principal works manager of the Central South African Rlwys., with headquarters at Pretoria, and had charge of the Pretoria, Johannesburg and Bloemfontein locomotive and car shops. This position he held until January, 1904, when he resigned and came to Canada, entering the service of the Canadian Pacific Railway Co. as inspector of improved methods at their Angus Shops, Montreal. After about two years, he joined the sales force of Messrs. Mussens, Ltd., as manager, and remained with that firm until his appointment in May, 1910, to his present position.

Mr. Press is also in charge of the layout and equipment of the new Quebec shops of the N. T. R. Previous experience in this class of work has, therefore, clearly stood him in good stead, as any one will admit who has visited the Transcona shops. The arrangement of the equipment and of the shops generally make this, without a doubt, one of the finest railway plants in America, and it should enable the Grand Trunk Pacific Railway to overtake repairs at a minimum cost. Mr. Press has as assistant engineers at Transcona, D. A. Evans, H. Pinch and A. D. Porter, all of whom are men experienced in railway shop work.

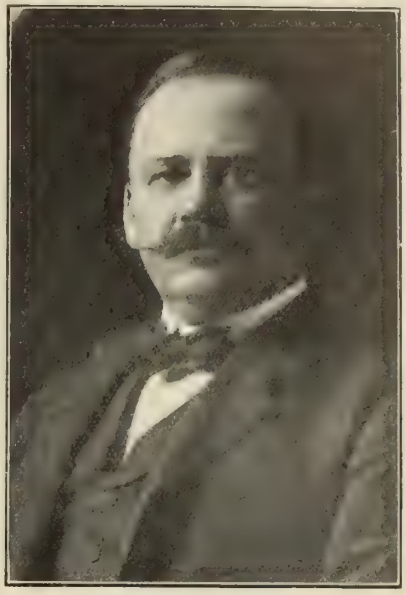
The contractors for the various buildings are Haney, Quinlan & Robertson, of Montreal; the work having been carried out under the direction of C. J. E. Maxwell, general superintendent. The contract for the supply and erection of the structural steel work was sub-let to the Manitoba Bridge and Iron Works, Ltd., Winnipeg; some 4,600 tons of steel having been used in the shops so far completed. The electric lighting and wiring have been installed by the Western Electric Co., and the tile conduits by G. M. Gest, Montreal.

General Layout.

The shops are located on the prairie, six miles east of Winnipeg, and the whole area occupied by the buildings and tracks has been covered by a heavy gravel fill, 3 feet 6 inches deep, in order to raise the shop floors sufficiently above prairie level, to avoid all trouble from flooding in the spring. The whole property is 2½ miles long by ½ mile wide, and the total floor area of the shops when completed will be rather more than 17 acres. The plant has been designed to allow of a future extension of 100 per cent., and always keeping this in view, the grouping of the shops has been arranged as compactly as possible in order to facilitate intercommunication in winter.

W. J. PRESS, Mechanical Engineer and Machinery Expert, N.T.R.

As in the majority of large railway plants of modern design, the various buildings are situated on either side of a spacious midway. Their location is clearly seen in the cut on page 188, which shows a bird's eye view of the whole plant, as it will eventually appear. The midway is 1,200 feet long, and runs north and south; a public road terminating it at the north end, while the locomotive roundhouse is located at the south end. It is served by a 10-ton electric traveling crane of 73 feet span, and by industrial and standard gauge tracks. The crane has a traveling speed of 400 feet per minute, enabling material to be rapidly handled between the various shops. It has two hoisting speeds of 15 and 40 feet per minute respectively. The motors, gears, etc., are covered in as a protection against the weather, and the operator's cage is electrically heated in winter. The height of the crane rails above ground level is 28 feet.



E. J. CHAMBERLIN.
President, the Grand Trunk Pacific Railway.

The power house, as will be noticed, stands about half way along the midway on the west side, thus occupying a central position for the distribution of power, light and heat. The track, running at right angles to the midway, immediately north of the power house and forge shop, forms roughly speaking, the dividing line between the locomotive and the car departments; the latter lying to the north and the former to the

south. The power house, foundry, pattern shop, stores house, and forge shop all lie to the south of this line, but, of course, cannot be said to belong to one department more than another, since they serve both equally.

Extending the full length of the midway there is a 5 ft. x 6 ft. tunnel to accommodate the high and low pressure steam pipes and returns, together with the compressed air lines, etc. Tile conduits branch off to the various shops, and a short subway connects the tunnel with the power house. In this way the various pipe lines are distributed throughout the plant. An auxiliary chamber runs outside the tunnel and carries the electric cable conduits which are embedded in concrete, and at convenient intervals open into chambers accessible from the tunnel by means of doors.

Needless to say, all departments are connected by telephone, the exchange switchboard being situated in the storehouse. Protection against fire is afforded by two 1,000-gallon Underwriter fire pumps in the power house, from whence a complete system of piping is distributed throughout the plant. Fire hydrants and hose houses are located in suitable positions about the yard, while inside the shops, reels carrying 50 feet of 2½-inch hose, with 1 inch fire nozzle attached, are affixed to the columns at convenient intervals.

Shop Lighting.

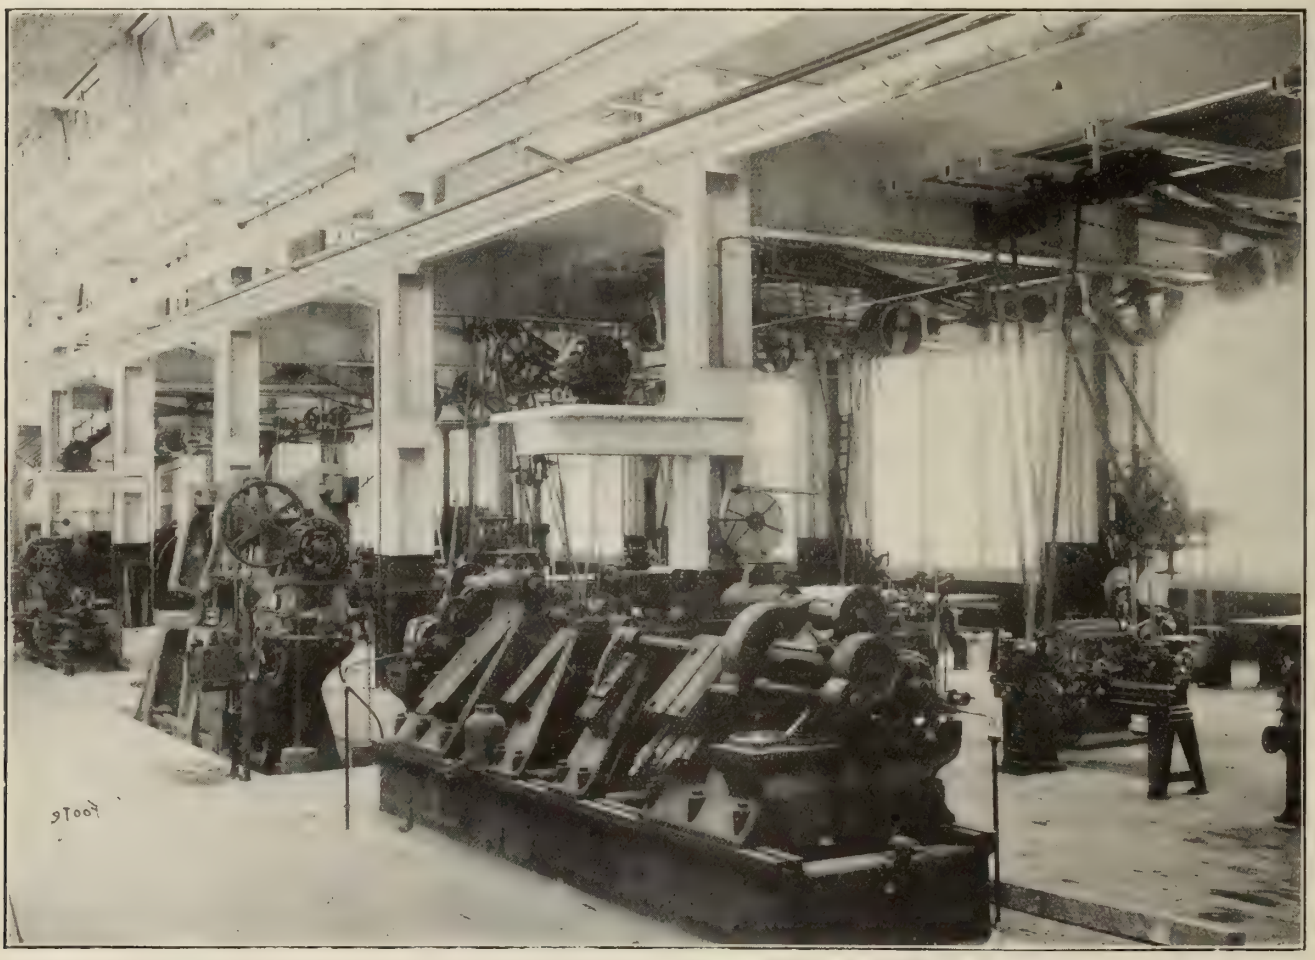
The general system of interior illumination is by Cooper-Hewitt A.C. mercury-vapor lamps of 700 C.P. each. Connections are also provided for incandescent drop lights and extension cables. A 600-volt feeder runs the full length of the midway tunnel with sub-feeders to transformers outside each shop. These reduce pressure from 600 to 200 volts to suit the mercury-vapor and incandescent lights. Throughout the shops already built, there have been installed 181 mercury-vapor lamps. These are all suspended high up in the roofs, well above the cranes, and are expected to give a steady light, free from shadow.

The midway and yards are lighted by Westinghouse series enclosed arc lamps. In the midway, these are carried from the crane runway, while in the yards they are supported by iron brackets on poles.

Details of Shop Construction, Foundations, etc.

Except in the case of the storehouse, stores platform and oil house, the buildings all have self-supporting steel frames standing on reinforced concrete footings. These are carried down 11 feet to the clay, and are of such a size that the pressure per square foot in no case exceeds 5,000 lbs. The walls are of concrete up to the window sills, and rest on wide concrete footings. Above the window sills, the walls are of white brick, carried up into a parapet wall on all four sides of the building and topped off with a coping of concrete. The roofs are mostly covered with tar felt and asphalt, coated with gravel. All windows are of ⅛-inch ribbed glass set in wooden sashes. The skylights are supported by ¼ x 3 inch steel ribs, and are of ⅜-inch wire glass, carried by rolled copper sheathing. Rainwater, etc., is collected on the roofs in copper receiving hoppers and brought down inside the buildings by wrought iron pipes to the sewers. The shop floors are of 3-inch planks spiked to 4 x 6 inch timbers, bedded in bituminous concrete.

The various departments are treated in the following pages in separate articles, forming a connected whole. Being very fully illustrated, they give a good idea of the appearance of the shops, while the equipment is described in considerable detail.



View in Machine Shop, looking south-east. Bertram Driving Wheel Quartering Machine in foreground. Next to it is the 600-ton Wheel Press. Above the quartering machine is seen a motor for one of the group drives below the gallery.

N.T.R. Locomotive Erecting and Machine Shops at Transcona

This important sub-division of the complete article refers to the design of the machine shop, the crane equipment, the erecting shop pits, the provision of compressed air, the window layout for natural lighting, the individual motor drives for heavy machines and the group drives for those of a lighter type.

THESE shops are contained in one large building situated on the east side of the midway. The building is 613 feet long and is divided longitudinally into three bays, having widths of 70, 60 and 40 feet respectively. The two latter bays, forming the heavy and general machine shops, will be dealt with later.

The 70 feet bay has a height to the roof truss chords of 50 feet, and forms the erecting shop. It lies on the north side of the building, and is arranged with twenty-five transverse locomotive pits, 43 feet long and pitched 24 feet centres. The bottom of each pit is lined with vitrified paving brick laid on edge, and has a slight fall to the north end, where a grating carries off all water to the sewer. The pit rails are laid on a continuous steel plate ½-inch thick, and are secured on the inside by 3 x 3-inch angles and steel clips, while on the outside, cast iron clips are used.

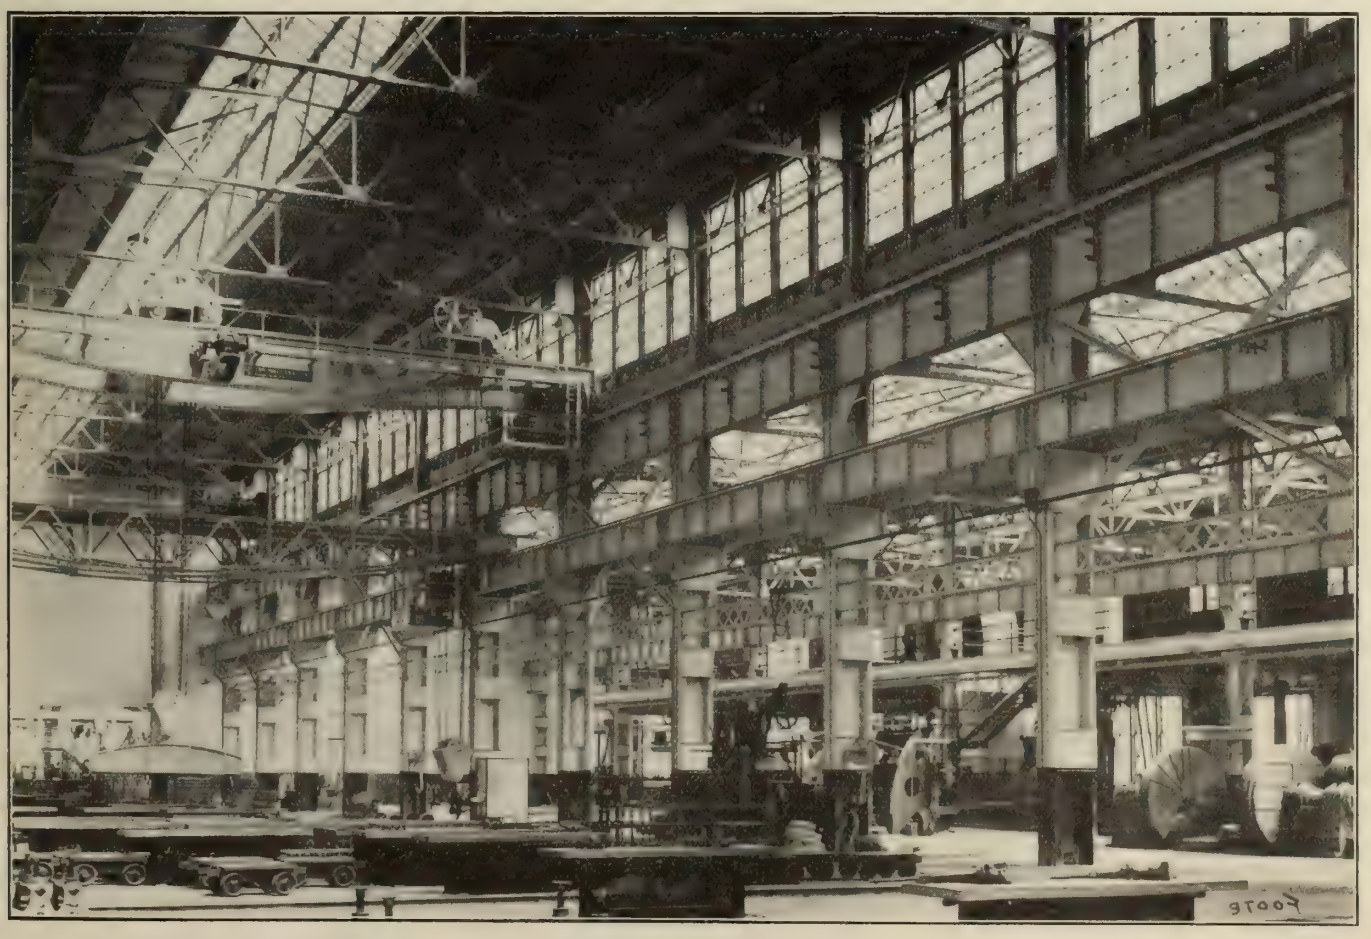
This is a great improvement on the usual method of fastening the rails to short ties. Each pit is provided at its south end with high pressure steam and water service pipes, while at the north end two ducts admit warm air; the shop being heated by the indirect radiation system. There are also four compressed air connections and two electric light sockets in every pit. Between the pits there are substantial work benches fitted with vises, drawers, etc., and having sockets for electric lights, while along the north side of the shop, at every fifth column, there is a motor driven 20-inch double emery grinder by the Bridgeport Safety Emery Wheel Co.

Locomotive Crane Equipment.

There are two entrances to the erecting shop, located at the sixth pit from each end. The locomotives come in from the south tracks through the machine shop, and are then picked up by a 120-ton electric traveling crane, and carried to any required pit. This crane was built by the Morgan Engineering Co., Alliance, Ohio, and is of the double trolley five-motor type; each trolley having a capacity of 60 tons. The span is 67 feet 6 inches and the lift 39 feet. Each main hoist is operated by a 52 H.P. motor, each trolley cross-traversed by a 15 H.P. motor, and a 52 H.P. motor runs the crane up and down the shop. All gears and pinions are of steel, and all bearings are provided with split bronze bushings. The motors are of General Electric make, and take 3-phase current at 550 volts, 60 cycles, direct from the power house feeders, as do all the cranes throughout the plant.

Booth Bros. Cranes.

Below the heavy crane there is a 10-ton messenger crane for handling the



Upper end of Locomotive Erecting Shop. On the upper runway is seen the 120-ton crane, and on the lower the 10-ton messenger crane. At the time this photograph was taken the work benches had not been distributed between the locomotive pits, hence the somewhat crowded appearance of the floor. The small trucks are for use on the industrial tracks in the Boiler Shop and elsewhere.

lighter material, such as cylinders, trucks, wheels, etc. This, a 3-motor crane with a span of 65 feet 2½ inches, was built by J. Booth & Bros., Ltd., Rodley, Leeds, England. It has a traveling speed of 300 feet per minute and a racking (cross-traverse) speed of 100 feet per minute. The load may be hoisted at 15 or 40 feet per minute, as desired. J. Booth & Bros. have supplied no fewer than eleven electric traveling cranes to the Transcona shops, and as they are all of the same general type, the present forms a suitable opportunity to describe their leading features. Their main girders are of the lattice type, stiffened laterally by lattice bracing attached to the outside of the end carriages. This makes a very rigid bridge and greatly reduces the tendency of the two ends of the crane to skew across the runway. The type of construction also gives a very wide platform from which to make adjustments, execute repairs, etc. Moreover, the lattice girders form a minimum of obstruction to the light from the skylights and windows, and hence tend toward a better lighted shop. The hoisting motion on these cranes is fitted with an overwinding device, which operates a switch in the hoisting circuit. It is also equipped with a patented mechanical brake, thus rendering it impossible for the load to drop at any point; in fact, the load cannot be lowered without sending reversing current to the hoisting motor.

There is also a mechanical brake, controlled by foot-lever in the operator's cage, for regulating the longitudinal traveling speed. The main rope sheaves are of the same diameter as the hoisting drums, thus ensuring an absolutely parallel lift. The hooks are of liberal dimensions, swivelling on ball bearings, and of sufficient weight to keep the ropes taut and prevent them buckling, when being lowered without a load. The Booth cranes are all equipped with motors manufactured by the Lancashire Dynamo & Motor Co., Ltd., and all fuses, switches, circuit breakers, etc., are entirely enclosed in order to eliminate any risk of accidental injury to the operator.

View looking west down Main Bay of Locomotive Machine Shop. Here are located the heavy individual motor-driven machine tools. This illustration gives a good idea of the appearance of the travelling cranes supplied by J. Booth & Bros., Ltd.

Locomotive Pits Equipment.

In addition to the two traveling cranes, the erecting shop pits are further equipped with bracket cranes hinged to alternate columns along the porth side of the shop. Eoch crane serves two pits, and is furnished with a 2-ton Yale & Towne triplex chain block. The bracket cranes themselves were supplied by the Whiting Foundry Equipment Co., and will be used for assembling, dismantling and front end work generally. The locomotive pits are, of course, situated midway between the shop columns, and their tracks are extended well into the 60 feet (heavy tool) bay of the machine shop, so that when the 120-ton crane has lifted an engine off its wheels, the latter may be run into the machine shop and there carried by the traveler to the wheel lathes, wheel press, etc.

Besides the air connections in each pit, similar unions are provided on the columns between the erecting and machine shops. Air is used at 100 lbs. pressure, the main compressor unit being located in the power house and described in that section. In order to help out the main machine and to equalize the pressure all over the system, three smaller units have been installed; one in the boiler shop, one in the machine shop (below the gallery) and one at the west end of the heavy machine shop. These three compressors are of the vertical quick revolution motor driven type, built by Bellis & Morcom, Ltd., Birmingham, Eng., and are fitted with that company's well-known system of forced lubrication. Each compressor has a duty of 660 cubic feet of free air per minute with a pressure of 80-120 lbs. per sq. inch, at 290 R.P.M., and is direct connected to a 150 H.P Lancashire Dynamo & Motor Co.'s

A.C. motor. Separate receivers are provided, these being located underground outside the shop. Laurie & Lamb, Montreal, supplied these air compressors and also the motors that drive them.

Natural Lighting Provision.

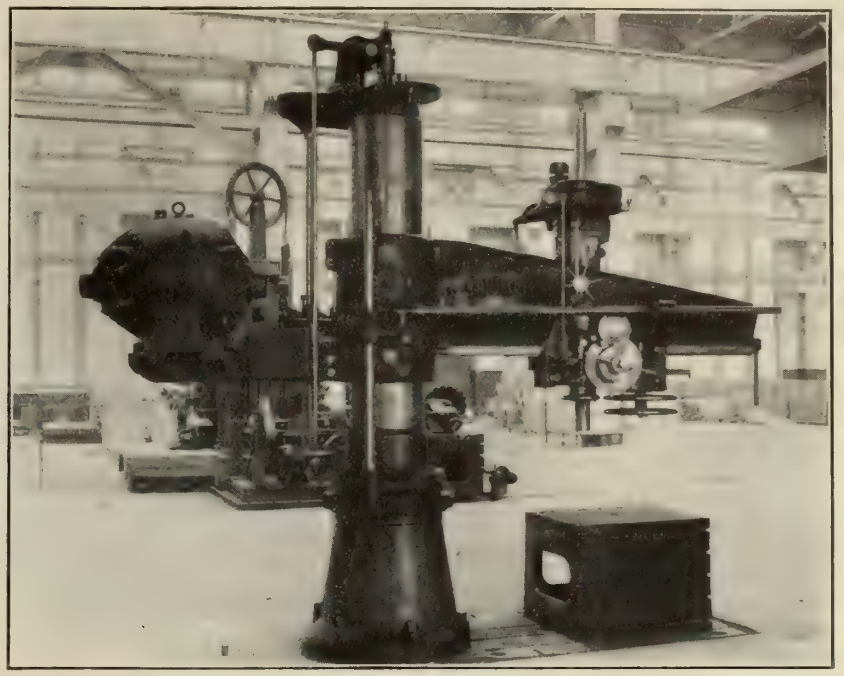
The natural lighting of the erecting and machine shops is excellent; ample window cases being provided in addition to skylights extending the full length of each bay. The upper windows can be opened and closed by chains from floor level, while the lower windows open by sliding vertically in the ordinary way. The bright and airy appearance of the shops is enhanced by having the interiors painted white.

The Locomotive Machine Shop.

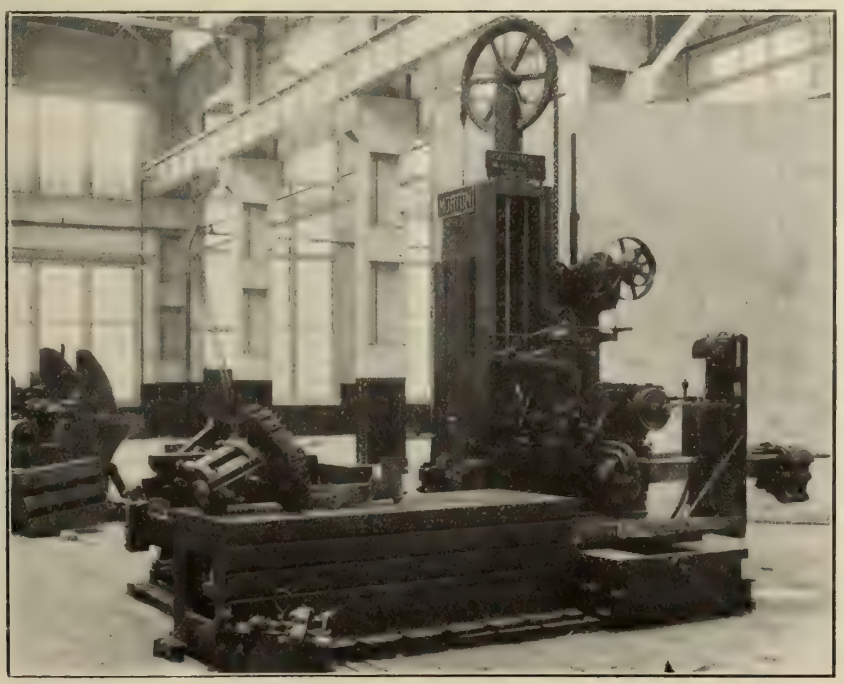
Opinions differ as to the best relative areas of machine shop and erecting shop floors. Among representative modern shops the ratio varies from .85 to 1.5. At Transcona the machine shop area, including the gallery, is 1.9 times that of the erecting shop; or if only that section of the gallery occupied by the brass department is included, the ratio is 1.45.

The machine shop, above mentioned, is in one building with the erecting shop, and consists of the centre and south bays of the building. The centre bay is 60 feet wide, while the south bay is 40 feet wide, with a gallery overhead. The centre or 60 feet bay is served by two Booth 10-ton cranes, similar to the messenger crane in the erecting shop, except that their traveling speed is 350 feet per minute, instead of 300 feet. The upper or east end of this centre bay is used for flue welding and tire setting, while the remainder of the bay is occupied by individual motor-driven machine tools.

The general layout of the locomotive erecting and machine shops may be seen from the plan on pages 194-195, which also shows the boiler and tank shop. The equipment of the flue department is very complete, and includes a Ryerson pit-type flue rumbler, fitted with chain cleaning device and driven by a 25 H.P. Lancashire motor. This rumbler is numbered 112 on the above mentioned plan, and is situated against the boiler shop wall. Near it are located the following tools: Ryerson combination hot saw and tube expander; Ryerson automatic safe-end cutting machine; Draper Manufacturing Co.'s pneumatic tube welder and swedger, and two oil-burning tube furnaces by F. Hyde & Co., Montreal. There is also an Underwood rotary flue cleaner, which will handle single 2-inch flues at the rate of 600 lineal feet per hour, and is intended as a standby in case of failure of the Ryerson rumbler. Nearby are the coppersmiths' and pipefitters' departments.



One of the many fine tools in the Locomotive Machine Shop—72-inch Central Thrust Radial Drill, by Wm. Asquith, Ltd.



The Morton Mfg. Co.'s 60-inch Draw-Stroke Cylinder Planer. On the table is seen the Rotary Planing attachment.

Tire Department.

Proceeding west down the bay, the tire department comes next. For expanding tires there is a 96-inch tire furnace, supplied by F. Hyde & Co. This is heated by crude oil and will take eight tires at once. Alongside this furnace is a large steel tire floor, where the tires are shrunk on the wheel centres. A little further down the shop is a concrete lye vat, 23 feet long by 7 feet 6 inches wide by 8 feet deep. This is heated by live steam coils arranged round the bottom, and is covered in by steel cover plates, which can be readily removed by the traveler. This vat will, of course, be used for cleaning the grease off side rods, driving boxes, etc., and is of ample depth to take a pair of large driving wheels if necessary. The following table gives particulars of the various motor-driven machines in this bay; index numbers correspond to those on the plan, pages 194-195. Where the main driving motor is stated as

being D.C., it is understood to be of the variable speed type.

From a study of the list below in conjunction with the plan shown on these two pages, the grouping of the machines in this bay will be readily followed. Thus, the machines for axle-box work (F. 43, 113 and 113 A) are situated near the tire floor. No. 113 is one of the Morton Mfg. Co.'s special 32-inch draw-cut railroad shapers, fitted with jib crane and hoist, and equipped with attachment for planing axle-box brasses. Planer 114 will also be available for axle-box work when not engaged on shoes and wedges, for which it is principally intended.

DETAILS OF MOTOR-DRIVEN MACHINES.

Mach. No.	Class of Machine.	Size.	Maker.	Motor.
F43	Forcing Press	50 tons	R. D. Wood	5 A.C.
113	Draw-cut Shaper	32-inch	Morton	7½ D.C.
113A	Slotter	12-inch	Bertram	5 D.C.
114	Planer	5x5x16 ft.	Canada Machinery Corporation	30 A.C.
115	Slotter	24-inch	Dill	7½ D.C.
116	Boring Mill	96-inch	Bertram	5 A.C. / 15 D.C.
134	Radial Drill	60-inch	Canada Machinery Corporation	7½ A.C.
117	Extension Gap Lathe	28-55 inch	Bertram	5 D.C.
119	Hydraulic Wheel Press	600 tons	R. D. Wood	10 A.C.
121	Quartering Machine	90-inch	Bertram	two 5 A.C.
120	Driving Wheel Lathe	90-inch	Canada Machinery Corporation	5 D.C. / 50 D.C.
122	Driving Wheel Lathe	80-inch	Bertram	30 D.C.
125	Planer	5x5x16 ft.	Redman	50 D.C.
126	Planer	5x5x16 ft.	Canada Machinery Corporation	30 A.C.
128	Draw-cut Shaper	26-inch	Morton	5 D.C.
129	Draw-cut Shaper	30-inch	Morton	5 D.C.
130	Boring Mill (Niles type)	72-inch	Bertram	3 A.C. / 15 D.C.

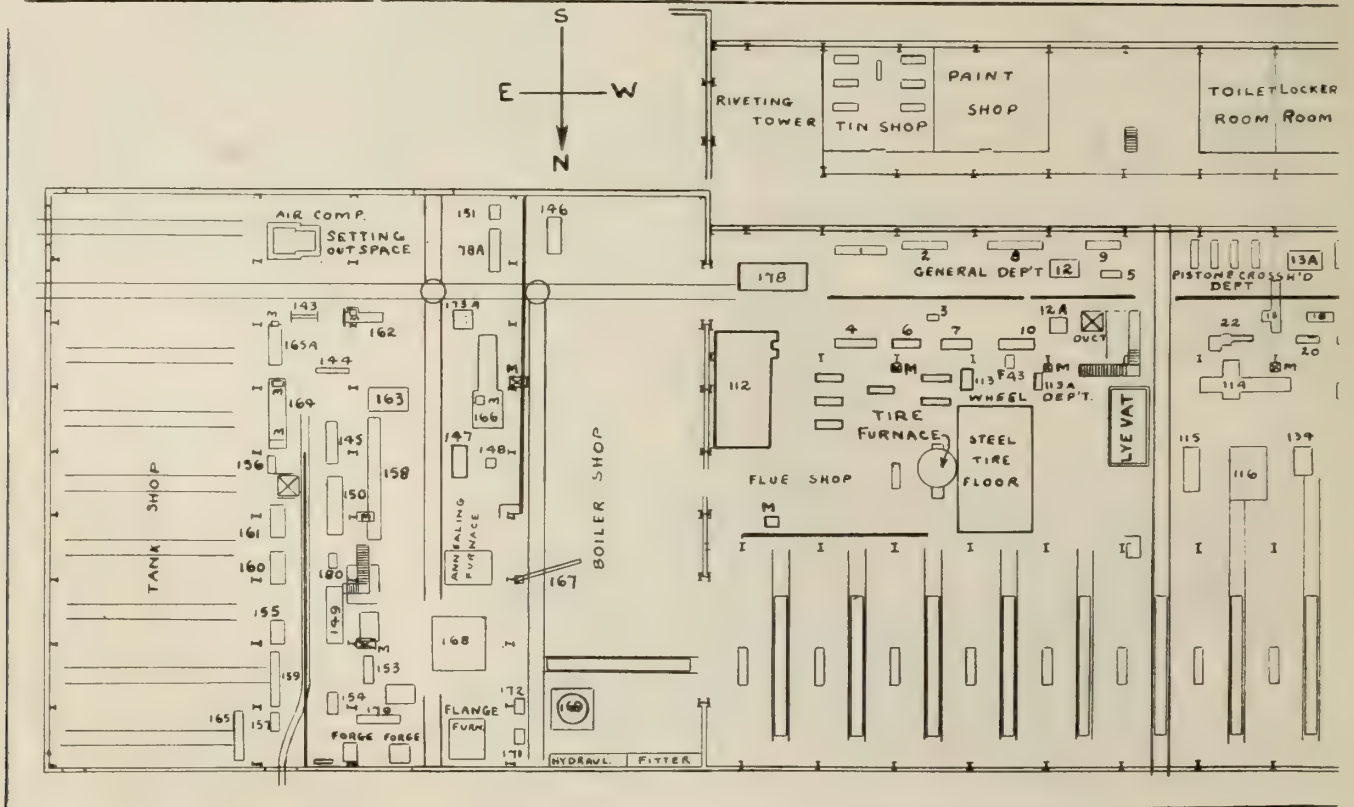
118	Radial Drill	72-inch	Asquith	10 D.C.
133	Draw-cut Cylinder Planer	60-inch	Morton	2 D.C. / 12 D.C.
135	Cylinder Borer		Bertram	15 D.C.
137	Draw-cut Shaper	26-inch	Morton	5 D.C.
136	Heavy Vertical Rod Miller	18-inch	Betram	10 D.C.
136A	Side Rod Drill	2 spindles	Bertram	two 10 D.C.
123	Heavy Slab Miller	3x3x14 ft.	Canada Machinery Corporation	30 D.C.

Wheel Department.

The wheel department comes next, and is fully equipped with 96-inch Bertram boring mill (116); 24-inch Dill slotter (115); two heavy wheel lathes (120 and 122); hydraulic wheel press (119); quartering machine (121); etc., etc. The Bertram boring mill is one of that company's latest type, fitted with friction cones for quickly cross traversing the heads on the cross rail and adjusting the tool bars vertically. The cross rail is raised or lowered by a 5 H.P. alternating current motor, while the mill itself is driven by a 15 H.P. variable speed motor.

The driving wheel quartering machine (121) is of the standard Bertram pattern, adjustable for any length of stroke from 16 to 40 inches. Each boring bar is driven by a 5 H.P. induction motor, and has two feeds and speeds and 12-inches traverse. This machine is equipped with a 2-ton jib bracket crane, as is also the 600-ton wheel press. The right hand head of the 90-inch wheel lathe is moved along the bed by an independent 5 H.P. motor operating through screw and friction gear drive; the function of the latter being to provide against breakage should the heads meet with any obstruction.

The tool posts are fitted with a powerful pneumatic clamp, shown on page 201. This clamp is designed to grip any tool used in turning tires. The vertical bolts are placed to allow of the broad forming tools being put in or taken out from either side. A double acting cylinder, taking air from the shop system, is contained in the body of the top slide. The piston operates through



PLAN OF LOCOMOTIVE, BOILER AND TANK

a rear bell crank lever A on the top clamp lever B, which in turn clamps the tool down upon its seat through a pressure plate C. A simple equalizing device is introduced between the top clamp lever and the pressure plate, so that the pressure on the tool is evenly distributed regardless of the setting of the adjustment nuts on the vertical bolts.

View in machine shop showing two of the automatic screw machines in Bolt Department

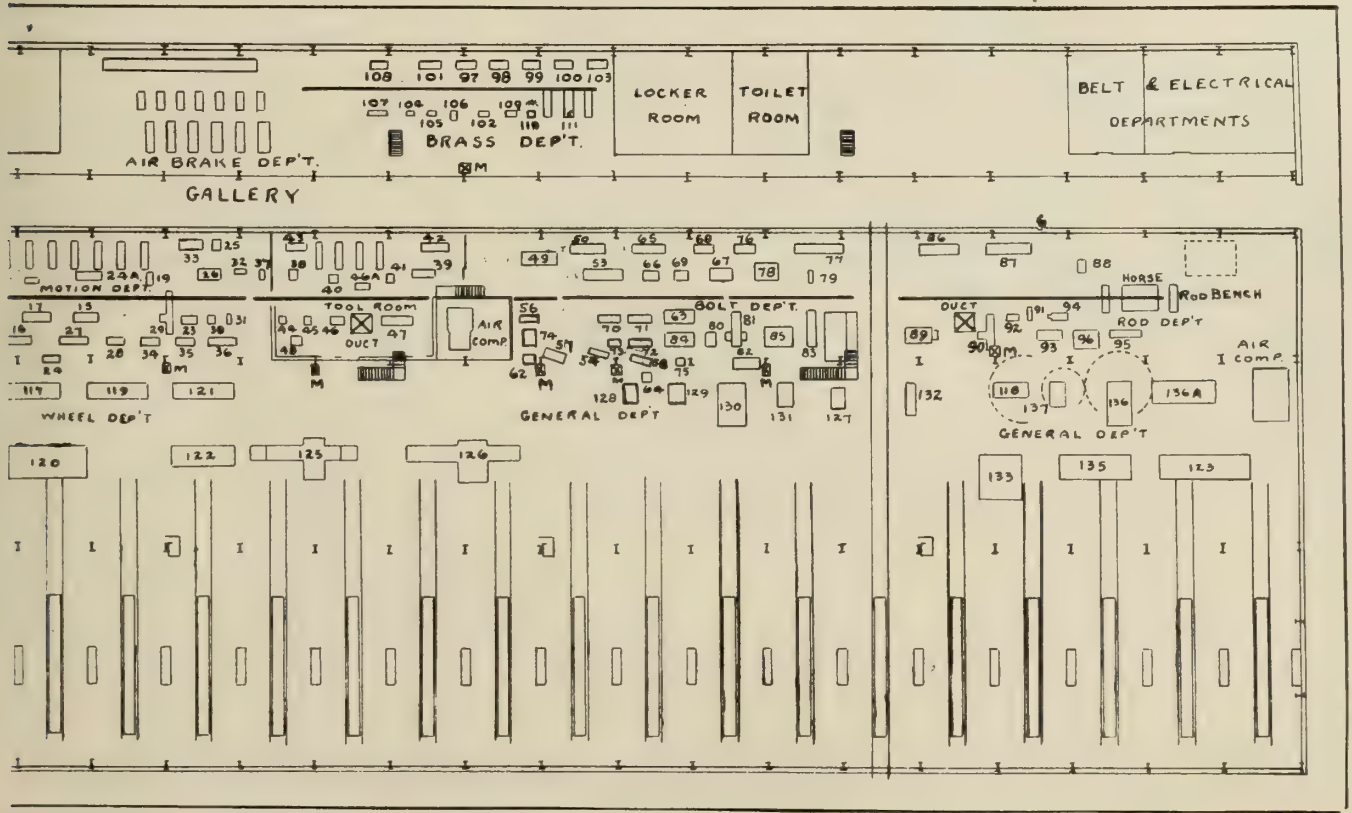
The clamp is controlled entirely by a single lever operating a four-way cock. Both wheel lathes (120 and 122) have the motor mounted on the left hand head, driving being direct through rawhide pinions.

Next to the wheel group, and in the middle of the bay, are the two 60-inch planers (125 and 126). These will be used for general work and are equipped with two side heads, in addition to the two heads on the cross rail. The centre of the bay for about 140 feet west of these planers is at present unoccupied and provides space for marking-off tables and storage of forgings, castings, etc., awaiting machining.

The south side of the bay at this point is occupied by a group of motor-driven tools for general work. These include 26-inch and 30-inch Morton draw-stroke pillar shapers (128 and 129). Each is provided with a jib crane and hoist and can take the special attachments supplied with the 32-inch machine (113) in the axle-box department. Next to these stand two boring mills for general work. The first (130) is a Bertram 72-inch mill with motor-elevated cross rail, and the other is by the Canada Machinery Corporation. The latter has a 42-inch table, fitted with combination 4-jaw chuck. This machine is equipped with foot power brake. Nearby is an Ingersoll heavy duty combination milling machine (127) with two spindles, one horizontal and one vertical. The drive is by a Morse chain from a 20 H.P. motor and is the only chain drive in the shop. This machine will be used for keyseating axles and general milling work.

Rod and Cylinder Work Department.

On the west side of the through track to the erecting shop are eight machines, which form what is classed as another general department, though they will be principally engaged on rod and cylinder work. No. 132 is an 18-inch Dill-type slotter by the Canada Machinery Corporation. Next to it is a very fine 72-inch radial drill of the central thrust type, of which an illustration is given on page 193. This drill was built by Wm. Asquith, Ltd., Halifax, England, and presents several features of interest. The portion of the arm in which the spindle works is of box girder form with walls of very stiff section. The spindle works midway between the walls, thus ensuring a central thrust. The thrust pressure on the spindle is taken by ball bearings and the arm, as may be seen, is counterbalanced by the



SHOPS, SHOWING ARRANGEMENT OF MACHINE TOOLS.

motor. The machine is double geared and is driven by a 10 H.P. variable speed motor, running at 300-1200 R.P.M. When in double gear, the spindle may be reversed, thus making it available for tapping and studding. This drill will be used for general and cylinder work, it being located near the group of cylinder machines.

Among other tools included in this group is a 60-inch Morton draw-stroke cylinder planer (133), equipped with special extension head and with port-milling and rotary planing, boring and milling attachments. The Morton cylinder planer is now to be found in a large number of railway shops, and needs no lengthy description here. Next to this planer stands a special Bertram cylinder boring machine (135), arranged to bore cylinder barrel and piston-valve chamber at one operation. Nearby is a heavy slab miller (123) which will be used chiefly on rod work. Opposite the two last mentioned machines are three others (137, 136 and 136A), all of which belong to the rod department. The first is a 26-inch Morton draw-cut shaper; the second a Bertram heavy duty vertical miller, and the last a Bertram double spindle side rod drill.

The 40 ft. Bay and Gallery.

The south bay of the machine shop, as previously mentioned, is 40 feet wide and has a gallery overhead. The machine tools in this bay are all belt driven and are divided up into nine groups. Each group, with the exception of No. 9 (at west end of bay) is driven by a 20 h.p., Canadian Westinghouse A.C. motor. Group 9 comprises the machines used for guide bar, rod and general work, and is driven by a 30 h.p. motor. All group motors throughout the plant take current direct from the power house circuits at 550 volts, 3-phase, 60 cycles, and are carried on wooden platforms supported by channel iron brackets riveted to the shop columns; the arrangement being clearly shown in the illustration on page 190. The location of these motors is indicated on the plan of the shop by the letter (M).

The nine line shafts below the gallery are in accurate alignment with one another, and wherever feasible, the ends of adjacent shafts are brought within about ½ inch of each other, so that should a group motor break down badly, it will be an easy matter to fit a coupling to the ends of the two shafts and thus drive the two groups by one motor until repairs are made or a new motor substituted. The main line shafting is all cold rolled steel, 2 15-16 inches diameter, and runs at 180 r.p.m. in Chapman double ball bearings supported in 24-inch cast iron hangers. The latter are carried by steel stringers formed of

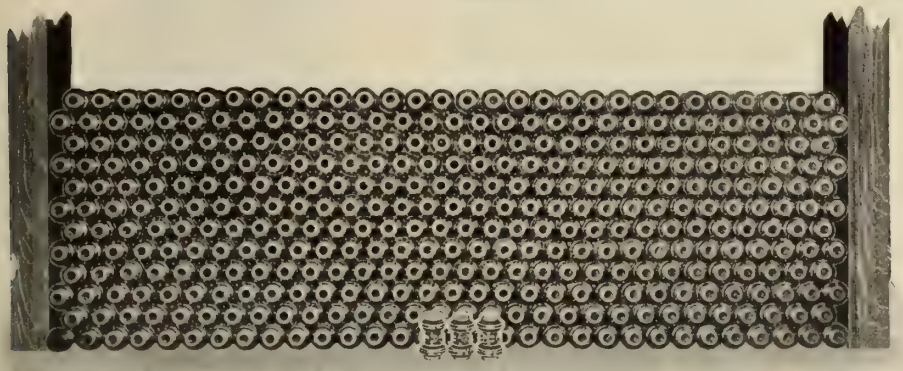
double 4-inch channels, which are locked to the gallery floor girders in such a way that it is impossible for them to slip, no matter how great the belt pull.

The Chapman Double Ball Bearings Co., of Canada, supplied all the ball bearings and hangers for the main line shafts throughout the plant; the total



A shipment of 369 Chapman Double Ball Bearings, 2 15-16 inch dia., for N.T.R. Shops, Transcona.

number of bearings in the order being 369. This is the largest installation of one size of this bearing in Canada and forms one of the largest orders ever filled by the company. The provision of these bearings was certainly a wise move on the part of the N. T. R., as by their use the friction eliminated will mean a yearly saving of many horse-power, besides a large economy in the matter of oil.

The main line shafts are equipped with split wood pulleys, specified to be "Dodge or equivalent make." The pulleys supplied with the countershafts of course vary, some being of steel, some of cast iron, and some of wood, according to the ideas of the firm supplying the machine which each one drives. The millwright work has been given much careful thought and attention; no belt drives are at less than 8 feet centres, and down belts all have a good angle. In no case is it necessary for an operator to go behind or to the side of his machine in order to reach the belt shifter, the latter in every case being located where he can easily handle it from the front. The same remark applies to the controllers for the motor-driven machine tools in the 60-foot bay, which are all in positions convenient to the operator's hand. Material is conveyed to and from the machines under the gallery by shop floor trucks. At a later date it may be necessary to put in an industrial track, a clear passage way having been left from east to west to allow of this. Each machine requiring such service is equipped with a traveling air hoist, placed in such a position that the operations necessary in handling material are reduced to a minimum.

General Department.

The table opposite gives particulars of the machines below the gallery; the groups being numbered from the east end. The plan of the shop on pages 194-195 clearly shows the class of work for which each group is primarily intended.

From foregoing list it will be seen that the equipment is all high class and conveniently laid out, with ample room round each machine. The tool room is situated about half way down the bay and is entirely enclosed from the rest of the shop by match boarding and expanded metal screens. No hardening furnaces have as yet been installed, but these will doubtless be added later. Adjacent to the tool room is the air compressor room, housing the Bellis & Morcom compressor already referred to. Above this room is the foreman's office.

The Gallery.

Access to the gallery is had by the three stairways indicated on the plan. These are of steel with concrete treads, and the floor of the gallery is also of concrete. The gallery does not extend quite the full length of the shop, 38 feet being cut off at the east end to form the boiler shop riveting tower, which will be described when dealing with the boiler and tank department. The gallery accommodates the tin, air brake and brass shops as well as the lavatory and locker rooms and the Sturtevant heating apparatus.

Tin and Paint Shop—Locker and Toilet Rooms.

At the east end is the tin shop, which is fully equipped with the usual tinsmiths' tools, including shears, groovers, formers, folders, etc. These were supplied by the Brown, Boggs Co., Hamilton, Ont., and others. Next to the tin shop is the paint room, where is stored the paint used in the locomotive and tank shops. To the west of the paint store stands one of the three sets of heating apparatus, to be presently described. Next comes a toilet room and locker room, each equipped with high class fixtures. The locker room, of which an illustration is given on this page, contains steel lockers arranged in two tiers and fitted with expanded metal doors. The wash basins in this room, and in all others throughout the various shops, are of porcelain, and have hot and cold water laid on. In addition to the two toilet rooms on the gallery, there are four urinal stands spaced at equal distances down the heavy machine shop at the foot of the columns dividing that shop from the erecting shop.

One of the Lavatory and Locker Rooms.

Air Brake Dept.—Brass Dept.

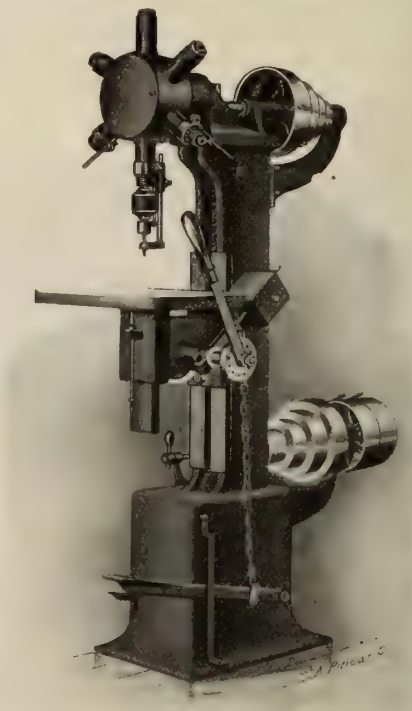
The next section on the gallery to be noted is the air brake department. This is served by a Canadian Rand air hoist

running on a hand operated traveler, enabling every part of the floor to be reached. The shop is equipped with standard Westinghouse testing apparatus, together with the usual stands for air pumps, etc. Next is found the second of the three heating units, and then comes the brass shop. The machines here are 15 in number, all operated from one line shaft. The latter is 2 15-16 inches diameter carried in 24-inch hangers fitted with Chapman double ball bearings, like the shafting below the gallery. Here again no wood beams or stringers are used; the hangers being suspended from channels supported by the roof trusses. This line shaft is driven by a 20 h.p. Canadian Westinghouse A.C. motor, and runs at 180 r.p.m. The brass shop has a length of 95 feet and contains the following machines:—

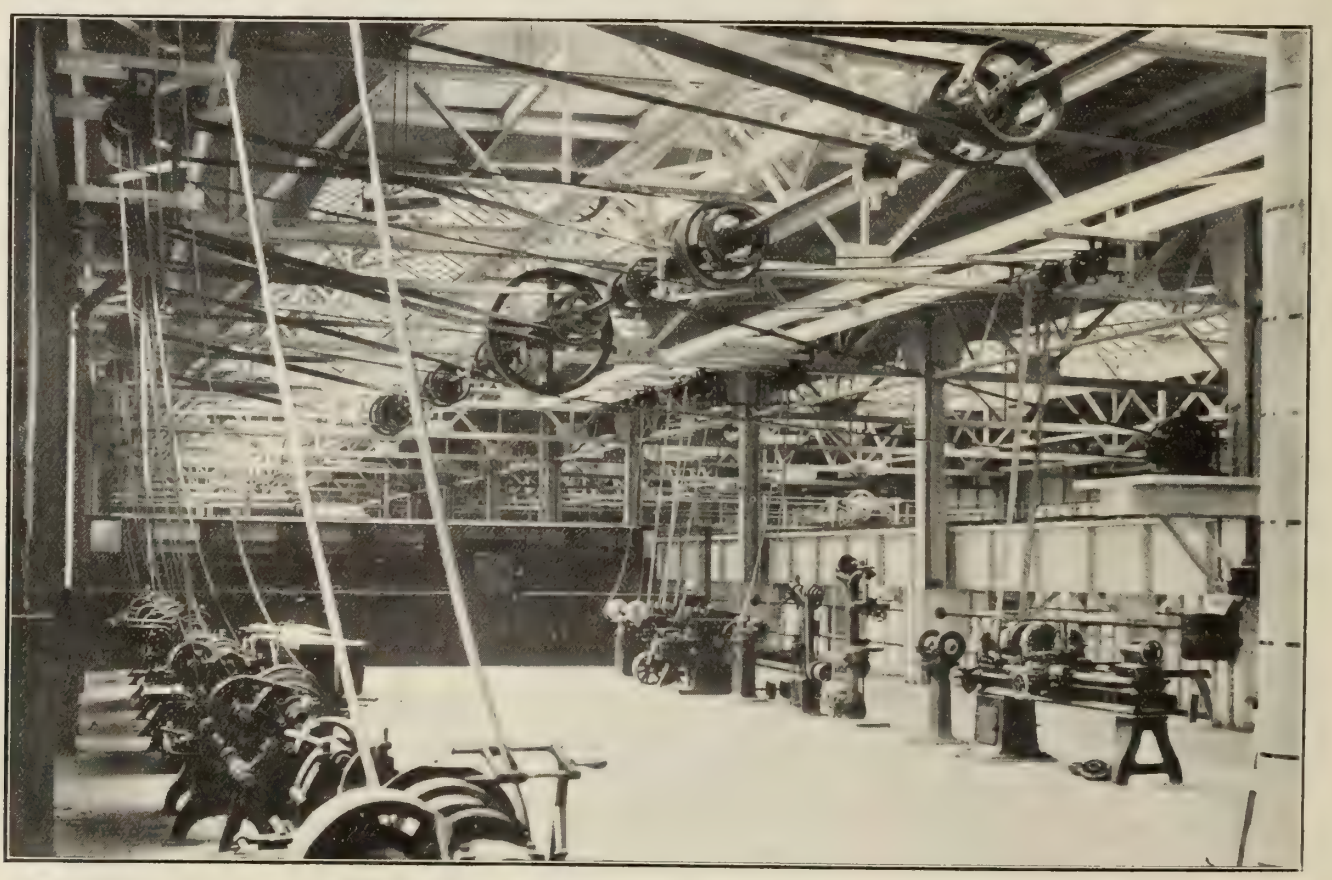
No. of Machine	Class of Machine	Size.	Maker.
108	Monitor lathe with taper attachment.	16"	Dreses Mach. Tool Co.
101	Geared head monitor lathe	18"	Alfred Herbert
97	Engine lathe	18"x6'	R. McDougall Co.
98	Geared head monitor lathe	18"	Warner & Swasey
99	Geared head monitor lathe	18"	Warner & Swasey
100	Geared head monitor lathe	18"	Warner & Swasey
103	Engine lathe with taper attachment.	18"x6'	Canada Machy. Corporation
107	Engine lathe with taper attachment.	18"x6'	Canada Machy. Corporation
104	Vertical drill press	24"	R. McDougall Co.
105	Turret drill	6 spindles	A. D. Quint
106	High duty crank-driven shaper	14"	Gould & Eberhardt
102	2-spindle miller	..	Warner & Swasey
109	Buffing machine	..	Bridgeport
110	Cock grinder	..	Warner & Swasey
111	Double emery grinder	18"	J. G. Blount

Immediately west of the brass shop is a second set of locker and toilet rooms; and next to these, the third heating unit. The remainder of the gallery is occupied by the quarters of the belt men and electricians. The three heating units on the gallery were supplied by the B. F. Sturtevant Co., and are designed to maintain the shop at a temperature of 60 degs. F., when the thermometer outside stands at 25 degs. below zero. The system is that of indirect radiation; large fans drawing in air between pipe coils heated by exhaust steam from the power house and by the fan engine exhaust, and delivering the heated air through vertical square steel ducts to concrete ducts below the shop floor, from whence it issues into the shop from openings along both walls under the windows and at the north end of each locomotive pit in the erecting shop. The vertical ducts are shown on the plan of the shop, page 195, and serve as a guide to the location of the heater units on the gallery above.

It must be remembered, when reading the lists of equipment, that these shops are intended to handle repairs only. No new locomotives will be built—for the present at all events.



One of the Quint 6-Spindle Turret Drills in Machine Shop.

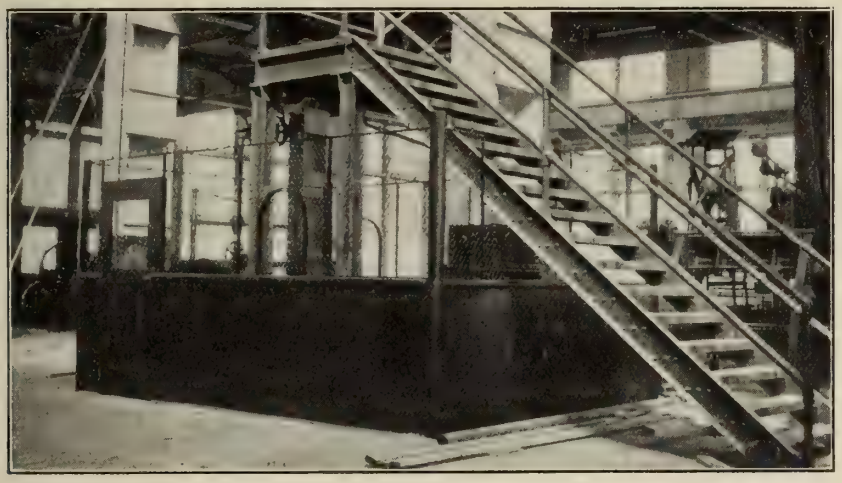


View of the Brass Department, situated on the gallery of the Machine Shop.

N.T.R. Boiler and Tank Work Departments at Transcona

Steel plate work enters so largely into the construction of the modern locomotive that an equally effective layout and equipment to that of the locomotive machine and erecting shops becomes a necessity. From the illustrations and detail data forming this article, it will be noted that ample provision has been made.

THE boiler and tank shop is one of the finest in the plant, and is situated at the east end of, and at right angles to, the locomotive shop, as may be seen from the plan on page 194. The shop is 180 feet long by 205 feet wide, and the height to the roof trusses is 36 feet. It is divided into four bays having widths of 65 feet, 30 feet, 50 feet and 60 feet respectively. The east bay (65 ft.) forms the tender tank repair shop and is served by a 20-ton Booth electric traveling crane. There are nine transverse tracks; tenders entering the shop by the second from the south, which is a through track to the riveting tower. The two tracks at the north end of the shop are used for truck work, thus leaving six tracks for tank repairs. Between each two adjacent tracks is a work bench with two vises, similar in every respect to those in the locomotive shop.



Boiler Shop Petty Stores. Stairs leading to gallery, where are located the toilet and locker rooms.

At the end of the two north tracks are located a 200-ton hydraulic car wheel press (165) and a 45-inch Bridgeford gap lathe (159) for refinishing truck axle journals without removing the wheels. This lathe is placed in a pit, bringing the gap on a level with the shop floor, so that any axle requiring to have its journals re-turned can be run on its wheels right into the lathe, a pneumatic jack being thereafter used to adjust it in the centres. The arrangement is clearly seen in the cut on this page. The lathe can also be used as a single end axle lathe; the head being moved along the bed by a rack and pinion so as to bring the wheel fit on the axle within the range of the carriage.

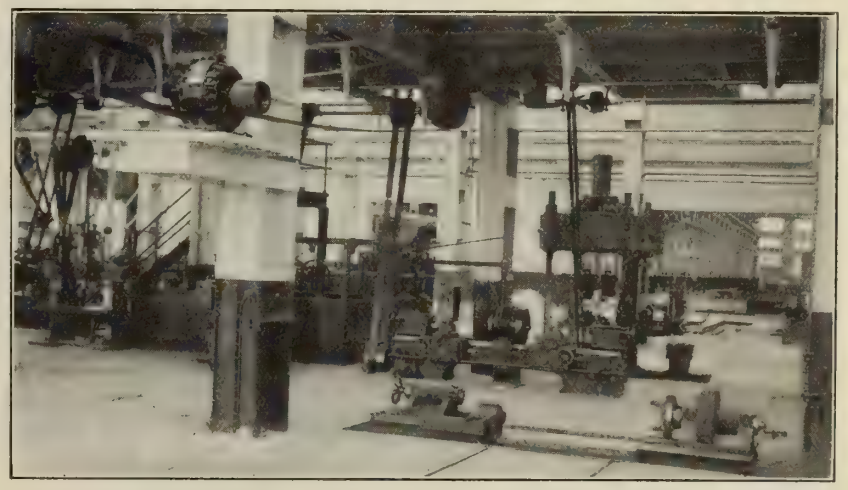
The 30 Ft. Bay.

The 30 ft. bay contains the machine tools for tender truck wheel, axle, and axle box work; the tools being divided into two groups and located under a gallery which extends rather more than half the length of the bay from the north end. This gallery is 20 feet above the shop floor level and carries the lavatory and locker rooms together with the Sturtevant heating apparatus; the shop being heated on the same system as the locomotive shop. A 5-ton electric traveling crane serves that part of the bay not covered by the gallery.

At the south end is situated the compressor room, which houses the Bellis and Morcom motor-driven air compressor referred to in the description of the locomotive erecting shop. The foreman's office is above the compressor room and is exceptionally large and well lighted; windows on all sides giving a clear view of every part of the shop. The line shafts and millwright work in this department are exactly the same as in the locomotive shop, but the machines under the gallery are served by an industrial track instead of by shop floor trucks.

30 Ft. Bay Machine Equipment.

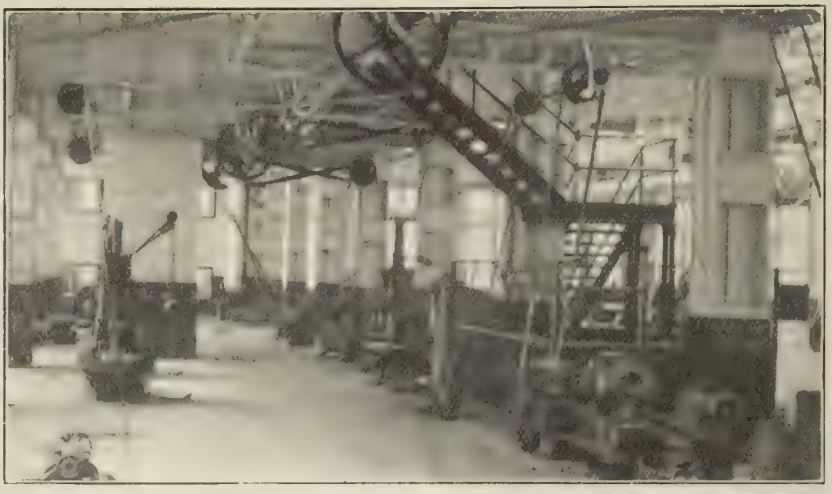
The truck axle boxes are bored out on a Bertram double spindle car box boring machine, having double carriages (165A). This is driven by a 10 h.p. variable speed motor and will bore four pairs at one operation. Next to this machine is a 42-inch coach wheel lathe (164) by the Canada Machinery Corporation; the chief feature of which is a central drive by means of steel pinions engaging with coarse internal gears behind the face plates. This lathe is fitted with pneumatic tool clamps similar to those on the heavy driving wheel lathe (120) in the locomotive machine shop. It is driven by a 40 h.p. variable speed Canadian-Westinghouse motor having a speed variation of 3 to 7, while the heads are moved in and out by two 3 h.p. alternating current motors operating through a reversing switch. A lathe of this type was fully described in Canadian Machinery in June, 1911.



View in Boiler and Tank Shop. Here is seen the Bridgeford gap lathe set in a pit, so that truck wheels and axles may be rolled in from the track in the foreground.

Dealing next with the tools below the gallery, group 12 is driven by a 30 h.p. motor and contains the following tools:

double axle lathe with central drive (149); 12-inch slotter (155); 45-inch gap lathe (159); 24-inch drill press (157); small punch (154); and 48-inch radial drill (153). Group 13 is driven by a 40 h.p. motor and consists of 6 feet bending rolls (145); double emery grinder (156); single axle lathe (150); two 42 in. car wheel boring machines (160 and 161); and one double spindle drill



View looking south below Boiler Shop gallery. On the right is seen the double axle lathe by Pollock & McNab.

(180). Beside the 48 in. radial drill (153), there is a pit to accomodate any work that would otherwise be too high for the tool.

The 50 Ft. Bay.

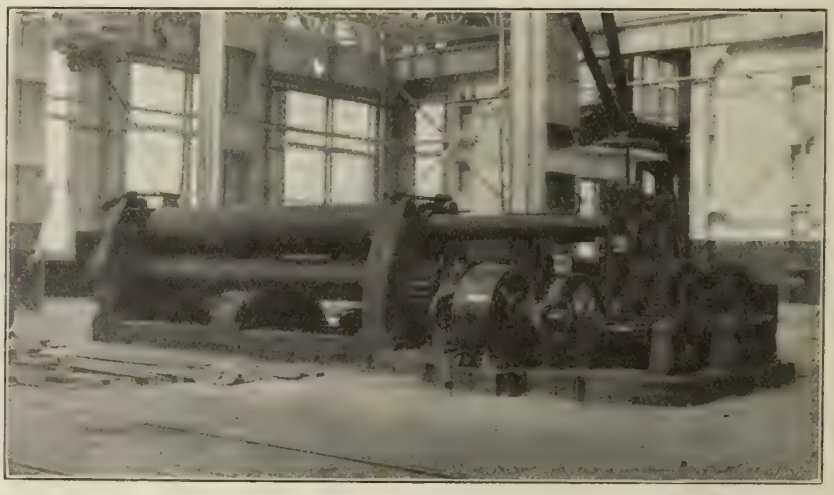
The 50 ft. bay is served by a 10-ton traveler, which like all the others in this shop was built by J. Booth & Bros. Ltd. It is occupied by the flanging press and furnaces, the large plate rolls and the heavy machinery generally. A standard gauge track runs down this bay with turntable connection to the through track. At the north end there is an angle iron forge and beside it an open forge, both supplied by F. Hyde & Co. Blast at 10 oz. pressure is supplied by a Canadian Buffalo Forge Co.'s No. 5 blower, seen on the plan against the north wall and beside the angle iron forge. It is belt driven from the line shaft in the 30 ft. bay.

Flanging is done on a 560-ton, 4 column, hydraulic press having 11 ft. 6 in. clearance. This is numbered 168 on the plan, page 194, and as may be seen, stands out so far towards the centre of the bay as to prevent the latter from being served by the standard gauge track throughout its full length. This, however was unavoidable, the foundations of the adjacent column rendering it imposible to set the flanging press further to the west. The press is by R. D. Wood & Co., who also built the accumulator for it. The latter has a ram 15 inches in diameter and a stroke of 15 feet. Besides serving the boiler shop it operates the boiler riveter and the hydraulic machines in the forge shop. It is served by two Gould 3 in. x 8 in. triplex pumps, driven by 40 h.p. Westinghouse A.C. motors. The working pressure is 2,000 pounds per square inch. The flanging press is served by a 12 ft. x 8 ft. fuel oil furnace situated about 15 feet to the north of it. There is a similar furnace for annealing purposes to the south of the press. Both are seen in the cut on page 201. They were manufactured by F. Hyde & Co., and, in common with the numerous other oil furnaces throughout the plant, are fitted with Jacob's low pressure burners, using fan blast pressure. The furnaces are lined with best quality Harbison-Walker refractory material, and are well designed in every way. The doors are operated by vertical pneumatic cylinders. Blast is provided by a Canadian Buffalo Forge Co., No. 12 steel pressure blower of the three-quarter housing type, with down discharge, connecting to the underground distributing pipe, which is placed 13 inches below the floor level. From the outlet of the blower, a large sweep elbow is thus allowed. The large blast pipe, increasing from 18 to 24 inches diameter, not only provides for future extension in case it is found necessary but also reduces the friction which is inevitably incurred wherever it is attempted to force air through piping at a high velocity. This blower is designed to deliver 10,000 cubic feet of air per minute, at a pressure of 16 oz. when running at 1,750 r.p.m., and is direct connected with flexible coupling to a 75 h.p. Allis-Chalmers-Bullock Co. motor.

A further special feature is the construction of blowers of this type for delivery of air at such a high pressure as 16 oz., and with a speed so low as 1,750 r.p.m. The desired results are secured by the use of a special narrow housing, with blast wheel of large diameter, and having a larger number of blades than in the ordinary design.

50 Ft. Bay Machine Equipment.

Of the machines in this bay the largest is No. 166,—the Bertram heavy plate bending rolls. These have a capacity for plates 14 feet wide and 7-8 inch thick. The upper roll is 24 inches diameter, and the lower rolls are 18 inches. The latter are driven by a 40 h.p. motor, and the upper roll is adjusted by worm gearing operated by an independent 12 h.p. motor. Plates are planed on a 24 feet plate edge planer (158), which is belt driven from the line shaft in the 30 feet bay and really forms part of group 13. This planer is fitted with hydraulic clamps in addition to the usual hand screw clamps. There is a Lennox rotary bevel shear (173A) for bevelling the edges of boiler plates that have to be caulked. This machine is driven by a 7½ h.p. motor. The only other motor driven tool in this bay, in addition to the heavy rolls (166) already mentioned, is (163) a single ended

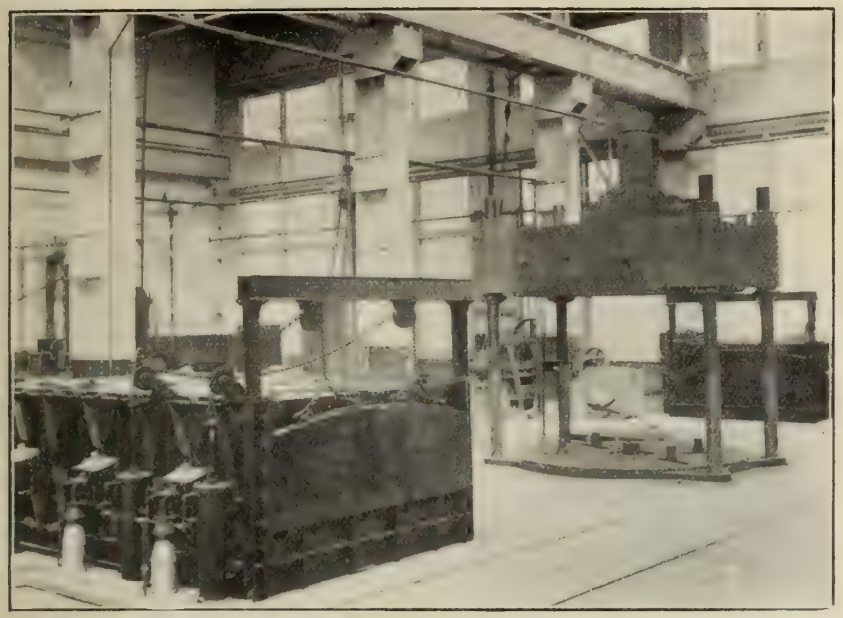


Bertram heavy motor-driven plate-bending rolls in Boiler Shop. Upper roll 24-in. diam. Lower rolls 18-in. diam. Distance between housings 14 ft. 2in. Motor 40 H.P.

punch or shear (convertible). It has a 36-inch throat and is driven by a 10 h.p. induction motor.

The belt driven tools in the 50-ft. bay form group 11 and are driven from a line shaft on the west side. The tools included in this group are numbered 78A, 146, 147, 148, and 151. Staybolts are threaded on 78A, which is a Lassiter 6-spindle staybolt machine. Right beside it is a small Foote-Burt 4-spindle drill (151) on which the tell-tale holes are drilled. Mud-rings are drilled on a Webster & Bennett 4-spindle drill (146), provided with pit, pump, etc. Further equipment in the boiler shop includes a pneumatic staybolt nipper and pneumatic staybolt breaker.

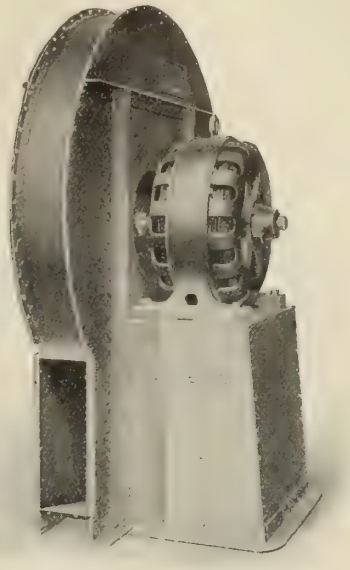
In laying out this shop, great care was taken to ensure that no machine when working on large plates, etc., shall interfere with the operation of neighboring machines.



A corner of Boiler Shop, showing 560-ton Hydraulic Flanging Press and Oil Furnaces. The Press is served by the Furnace in the Background.

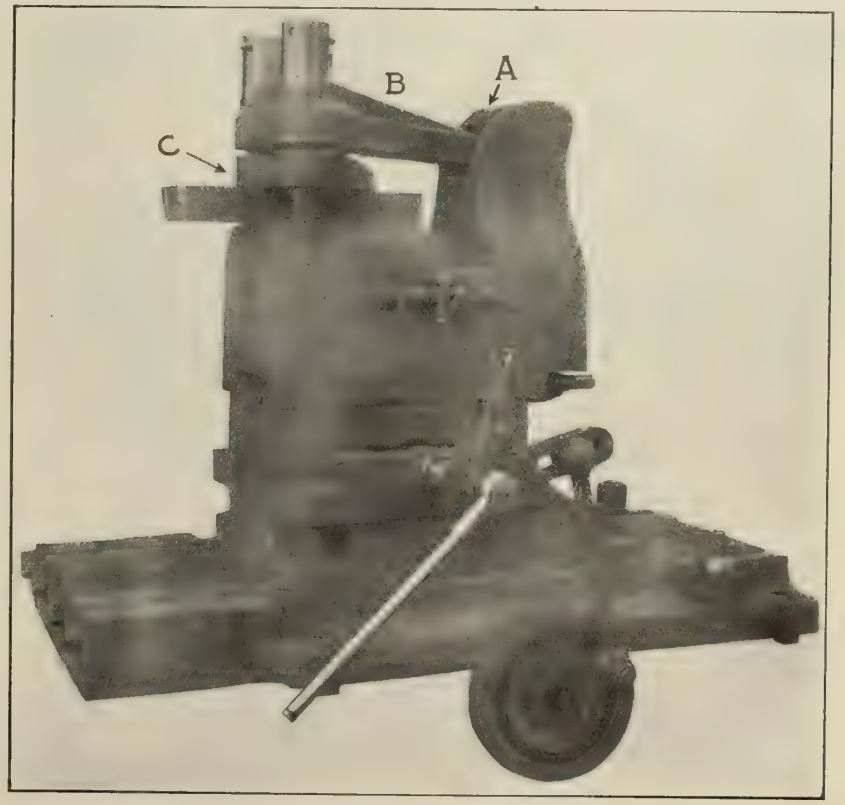
The 60-Foot Bay.

Boiler assembling is done in the 60-foot bay, which is that next to the locomotive shop wall. This bay is served by a 30-ton electric traveling crane and by a standard gauge track down the east side. After being assembled, boilers are carried by the traveler to a truck on the through track at the south end of the shop, and run to the riveting tower. This, as previously mentioned, is situated at the east end of the 40-foot bay of the machine shop. The hydraulic riveter (178) has a gap of 18 feet 6 inches, enabling the largest boilers to be riveted up without turning over. This machine is believed to be the largest of its kind in Canada at the present time, and weighs 112,000 lbs.



Canadian Buffalo Forge Co.'s No. 12 Steel Pressure Blower.

One of the Canada Machy. Corporation 42-inch car wheel boring machines in Boiler and Tank Shop. It is equipped with a pneumatic hoist.



Pneumatic tool clamp fitted in Canada Machinery Corporation 90-inch driving wheel lathe, and 42-inch coach-wheel lathe.

It was built by R. D. Wood & Co., Philadelphia, and is of the triple power outside packed type of 50, 100 and 150 tons capacity. A 20-ton electric crane serves the riveter, and is entirely controlled from the riveting platform, which is of sufficient size to give ample room for the operators, rivet furnace, etc.

The boiler shop is fully equipped with complete sets of staybolt taps, reamers, etc., manufactured by A. B. Jardine & Co., Hespeler, Ont., while the numerous pneumatic tools in this and the locomotive shop were supplied by the Holden Co., Ltd., Montreal, and include Little Giant tube expanders and air drills; New Boyer holders-on, riveting and chipping hammers; and a Chicago 12-inch spread jaw pneumatic riveter. There is also full provision of sledge hammers, wrenches, ratchet drills, oil burners and necessary general equipment. The 50-foot bay is provided with two 6 feet by 9 feet surface blocks, shown on the plan, but not numbered.

The hydraulic accumulator (169) stands at the north end of the 60-foot bay, and the two pumps (171 and 172), which, of course, are automatically controlled, stand close by. All hydraulic machines exhaust back to the tank, so that the same water is in use all the time. In front of the accumulator is a pit over which the finished boilers are placed when receiving their hydraulic and steam test, before passing to the erecting shop.

The table on this page gives particulars of the machine tool equipment.

The cranes in this shop all have a maximum traveling speed of 250 feet per minute, with the exception of the 20-ton crane in the tank department, which has a speed of 200 feet. The racking speed is 100 feet per minute in every case, and except in the case of the 5-ton crane serving the south end of the 30-foot bay, each crane has two hoisting speeds.

The floor is of 3-inch planking, spiked to timbers set in bituminous concrete, similar in every way to that in the locomotive shop.

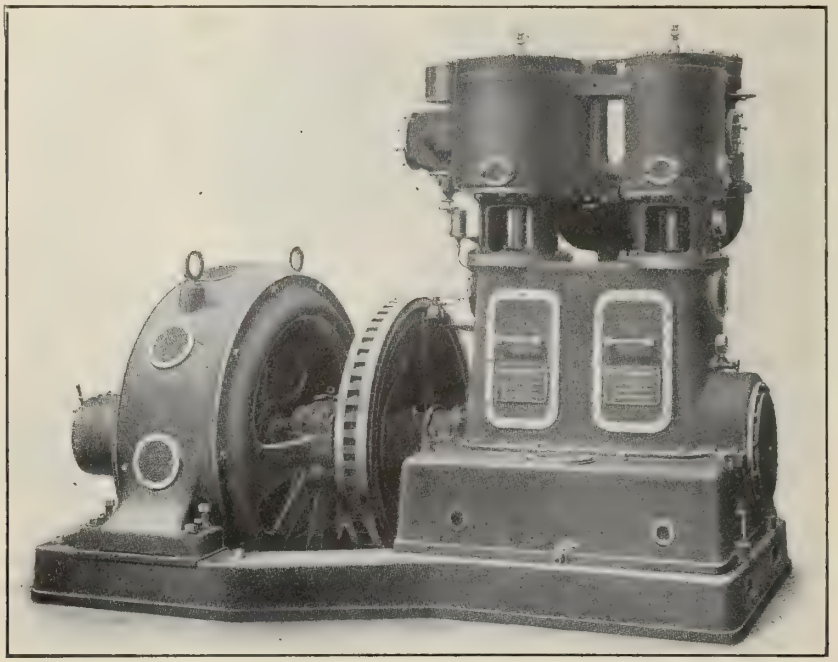
The Forge Shop, Forge Stores, and Scrap Bins

This department is centrally located in order that it may conveniently serve both locomotive and car departments. The lay-out is good, the location of the jib cranes, hammers and furnaces having been given very careful consideration.

THE forge shop is 260 feet long by 100 feet wide, and is spanned by a single truss roof, as dictated by the best modern practice. The elimination of intermediate supporting columns allows free scope in the distribution of equipment and facilitates the placing of the swinging jib cranes in the most suitable positions for serving the hammers and furnaces. This shop is well lighted by side and end windows, the upper panels of which are pivoted to give ventilation. The lower sashes can also be raised in summer, and further light and ventilation is afforded by the monitor, which extends the full length of the roof. The shop has a floor of wall-tamped cinders, and is heated by direct radiation, the steam coils being arranged along the walls below the windows. There being no overhead cranes, the wall columns of this building are of lighter construction than in the locomotive shop, since they have only the roof truss loads to carry. The building is very rigidly tied by struts and lateral bracing to counteract vibration caused by the steam hammers and the stresses set up by the jib crane loads.

As may be seen from the view on page 188, the forge shop lies immediately to the north of the locomotive shop, being situated between it and the



One of the three Belliss & Morcom two-stage, motor-driven air compressors.

eventual position of the car machine shop. It is thus able to conveniently serve both departments. The floor is well covered by industrial tracks, with turntables at each intersection, and the layout of the equipment is seen in the plan on page 204. The end of the building facing on the midway is to the left or west side. A small two-storey annex on the south accommodates the toilet and locker rooms.

Spring Dept.

The south-west corner of the shop is devoted to making and repairing locomotive and car springs. The furnaces in this department, and throughout the shop, all burn fuel oil and were manufactured by F. Hyde & Co., Montreal. They are fitted with low pressure burners similar to those in the boiler shop. The blower for the spring department is designed to deliver 4,800 cubic feet of air per minute at 14 oz. pressure when running at 1,750 R.P.M. It is a Canadian Buffalo Forge Co.'s No. 7 special steel plate blower, direct connected to a 40 H.P. Allis-Chalmers-Bullock A.C. motor. The spring furnace is equipped with the usual oil-quenching baths, racks, etc., and every convenience is at hand for turning out springs rapidly and economically. A full list of the equipment is given on page 205, the machine numbers corresponding with those on the plan on page 204.

Hand Forges.

The south side of the shop, east of the spring department, is occupied by a row of thirteen double forges, by F. Hyde & Co. These are spaced 15 feet apart on a centre line 16 feet 9 inches from the wall, and, as may be seen, are set at an angle to facilitate the handling of long stock. Such an arrangement results in a very considerable saving of floor space, and of course reduces the necessary stacks and holes in the roof by one-half. Each forge is fitted with an automatic valve, by means of which the gases generated when the fire is damped down can escape freely to the atmosphere. Where no such provision is made, the gases accumulate in the blast pipe and are liable to cause an explosion in the latter when the fire is rebuilt. In order to obtain an even temperature, running water is piped to the cooling tanks attached to each forge, the overflow being carried to sewer. Each forge is well equipped with the necessary tool racks, etc., and has a 400-lb. anvil.

The frame forge is seen on the plan, just south of the industrial track turntable in the centre of the shop. It is of the drop type, operated by a pneumatic jack. When the locomotive frame is being heated the forge is in its elevated position; but when the correct heat has been attained, the forge is dropped and the frame swings away, without the necessity of raising the cranes. This is a great improvement upon the usual method, which involves more or less dragging of the frame through the coal on the forge, thus getting dirt in the weld.

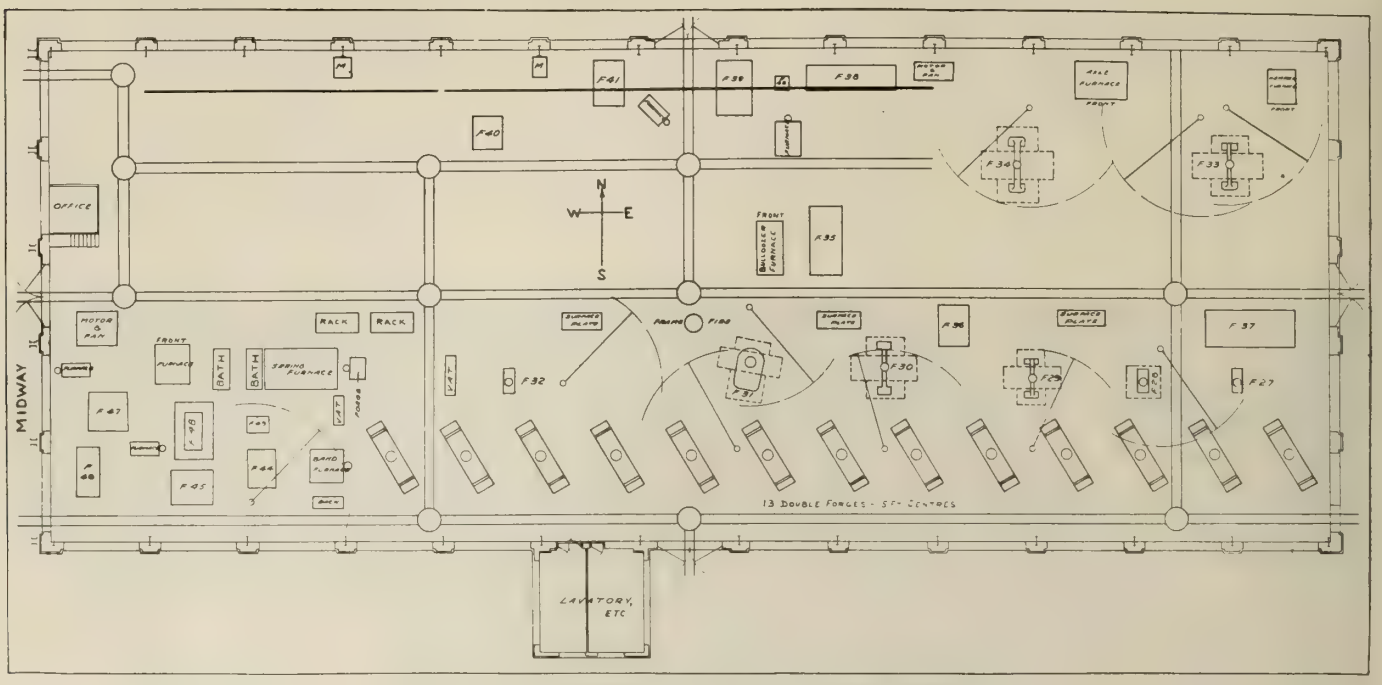
SOUTH SIDE OF FORGE SHOP, SHOWING SPRING DEPARTMENT.

Hammers, Cranes, Etc.

In front of the row of double forges there are six hammers, varying from 200 lbs. to 3,500 lbs. The frame hammer (F31) is of the latter weight, and is set at an angle best suited to serve the frame fire. The jib cranes were all supplied by Geo. Anderson & Co., Ltd., Montreal; their location is indicated on the plan. In addition to the necessary surface plates, etc., this part of the shop

is equipped with a vertical hydraulic bar shear (F36) and an alligator shear (F37) direct driven by a 25 H.P. motor. In the northeast corner are two hammers and furnaces for the heavier work. One of these (F33) is 3,500 lbs., and the other (F34) is 5,000 lbs. The John Bertram & Sons Co., Ltd., built all the hammers with the exception of that marked F32; this is a 200-lb. single frame hammer by Thwaites Bros., Ltd., Bradford, Eng. It was found necessary, owing to the nature of the ground, to pile all the hammer foundations. To accommodate the steam, exhaust, hydraulic, water and fuel oil lines, there is a concrete duct running up the middle of the shop from the midway tunnel and powerhouse. Branches connect with the hammers, furnaces, hydraulic shears, etc.

In the centre of the shop is a powerful hydraulic bulldozer (F35) with oil furnace adjacent. Along the north side of the shop are ranged the forging machines and a heavy axle cutting-off and centering machine (F38). The latter



PLAN AND EQUIPMENT LAYOUT OF FORGE SHOP.

North side of Forge Shop. This shop serves Locomotive and Car Depts. As may be seen, ample space has been provided for further equipment when the Car Shops are completed. The machine in the foreground is a hydraulic bar shear by R. D. Woods & Co.

is fitted with two heads and carriages, and centering attachment; its capacity being 12 inches diameter by 14 feet. These machines are driven from line shafting divided into two groups, each driven by a 40 H.P. motor. The shaft at the west end is at present idle, having been provided to drive further equipment, which will probably be installed in the forge shop when the car shops are completed. The manner in which the line shafts are carried from the roof trusses, and the countershafts from light lattice girders bolted to the wall columns, is clearly seen in the illustration at foot of page 204. The shafting equipment here is the same as in the other shops, viz: 2 15-16 inch shafting, 24-inch hangers and Chapman double ball bearings.

There are three blast fans, each direct motor driven. That in the spring department has already been described. The other two are of the same style and make. One is a No. 12 blower exactly similar to that in the boiler shop, and the other is a No. 8 blower, designed to deliver 6,400 cubic feet of air per minute at 14 oz. pressure. It is coupled to a 50 H.P. Allis-Chalmers-Bullock Co. motor and runs at 1,750 R.P.M.

Forge Stores and Scrap Bins.

Behind the forge shop are the forge stores and scrap bins. The general style of this building may be gathered from page 188, where it is numbered 11. It is a wooden frame structure 220 feet long by 30 feet wide. The eastern half consists of a raised platform, roofed in and divided into suitable bins for the reception of the various grades of scrap. The other half forms a store for the rods, bars, etc., used in the forge and also for the coal and coke. For the former there is an extensive system of stout racks, while the latter are stored in bins. Hatches are fitted in the roof above these so that the yard crane may unload cars direct into the bins by means of an orange peel bucket. The store is served by a continuation of the industrial track system from the forge shop, so arranged as to reduce to a minimum the amount of handling necessary in transferring stock from the iron rack to the forge.

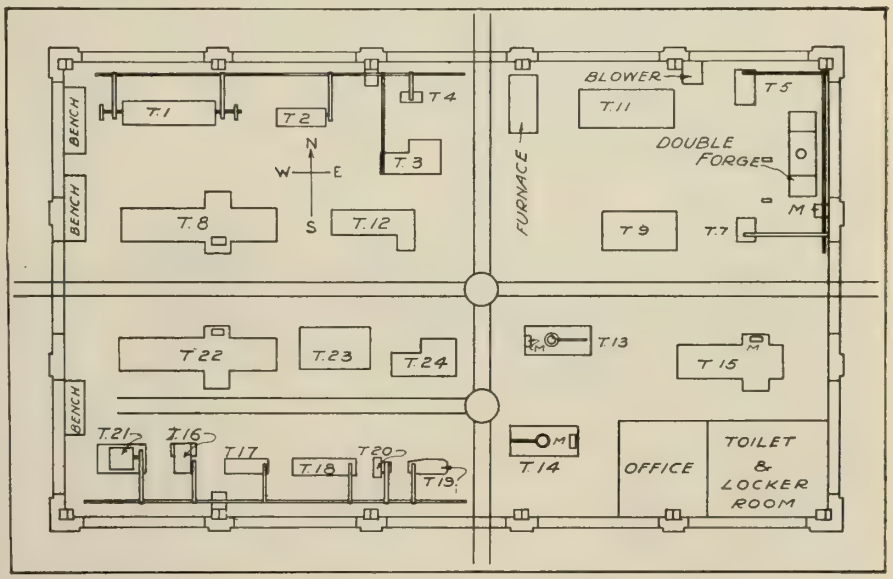
The Frog and Track Shop and Crude Oil Storage

Not the least important department in a modern railroad headquarters plant is that devoted to the maintenance and repair of frogs, switches and track work generally. The Transcona frog shop is not designed for turning out new work; a comparatively small building is consequently sufficient to accommodate the various machine tools used in this class of track work.

THE frog and track shop, number 9 on page 188, stands about 250 feet east of the forge shop. The nature of the work done here calls for no interchange with other departments, hence, there is no necessity for a location on the midway, the shop being an entirely self-contained unit. It is 100 feet long by 60 feet wide and has a height of 24 feet to the lower chord of the roof trusses. It is spanned by a 10-ton Booth electric traveling crane, having the following speeds per minute: traveling, 200 feet; racking, 100 feet; hoisting, 15 feet and 40 feet. The shop has the usual 3-inch wood floor, and is served by industrial tracks. A standard gauge track will doubtless be brought into the shop at some future date to enable the finished frogs and switches to be loaded by the traveler direct onto flat cars. Ample natural lighting is provided by large window and skylight areas, while artificial illumination is by mercury-vapor lamps, as in the other shops.

Owing to the nature of the work turned out, no great head room is required in a frog shop; and in the present instance, the height to the roof truss chords, as above mentioned, is only 24 feet; the crane runways being correspondingly lower. The limited headroom available has necessitated carrying the line shafts about 4 feet above the floor, the drive being upwards to countershafts above. In this way only could sufficient length of drive be obtained for all belts. The main line shafts run in Chapman double ball bearing pillow blocks, supported on gusset brackets. The latter are riveted to a light lattice girder carried by the wall columns the arrangement being similar to that employed in the forge shop. The countershafts, as may be clearly seen in the illustration, are carried by brackets from the crane runway girders; the crane operator's cage being brought out to clear them. The foreman's office and the locker rooms, etc., are in the southeast corner of the shop, and are enclosed by a wall 8 feet high only, to



LAYOUT OF FROG AND TRACK SHOP.

allow the crane to pass overhead. The office has a light roof, but the lavatory is open. The building is heated by direct radiation; the steam coils being arranged along the walls below the windows.

In the north east corner there is a double forge similar in every way to those in the forge shop. This forge is served by two belt driven strap hammers (T5 and T7) of 200 lb. and 125 lb. weight respectively. These will handle all the blacksmith work in the shop. The planers and other heavy machines have individual motor drives and occupy the body of the shop; while the lighter tools are arranged along the north and south walls and driven from line shafts. The accompanying table gives particulars of the equipment.

The bulldozer (T11) is served by an oil furnace supplied by F. Hyde & Co., and is equipped with jib crane, as are also the two strap hammers. Blast is obtained for the forges and oil furnace from a Canadian Buffalo Forge Co.'s No. 5 steel plate blower. This is direct connected to a 25 h.p. motor, running at 1750 r.p.m., and has a duty of 2,700 cubic feet of air per minute at 14 oz. pressure.

Crude Oil Storage.

Crude oil is stored in a concrete building close beside the north side of the frog shop. To avoid risk of fire, the building is sunk in the ground nearly its entire depth, the walls only projecting some two feet above ground level. Its inside measurements are 60 feet long, 25 feet wide and 10 feet deep. The roof is of concrete supported by steel beams. Inside are four horizontal cylindrical steel tanks, each having a capacity of 8,000 gallons. They are fitted with large pipe necks extending to the outside of the building by means of which they are filled from tank cars on the adjacent track.

Pumps are not used for distributing the oil to the various shops; instead, compressed air is piped to each storage tank and the oil is thus forced all over the system. The air connection to any tank can of course be cut off to allow of filling.

This system probably makes for cheaper distribution than would be the case if pumps were used, but would seem to present greater risks of breakdown. If anything goes wrong with the air supply, the whole plant is deprived of oil; whereas with pumps each shop may be made a separate self-contained unit.

INTERIOR OF FROG AND TRACK SHOP.

Central Power House Equipment, N.T.R. Shops, Transcona

The growing appreciation of the paramount importance of having a thoroughly efficient and reliable power plant equipment form an integral part of every type and extent of manufacturing effort is amply demonstrated in the subject matter of this article. It is here shown that requirements have been wisely and carefully forecasted, and as a result, perusal of the details forms an attractive and educative exercise for every class of our readers.

THE power house, like the other principal buildings, is a self-supporting steel structure, with walls of concrete as far as the window sills, from which point up they are of white brick. The building is 150 feet long by 110 feet wide, and is divided longitudinally by a brick fire wall into two parts 45 feet and 60 feet wide. The smaller part forms the boiler house, and the larger the engine room. The boiler house contains eight water tube boilers, by the John Inglis Co., Ltd., Toronto. They are of the Erie City vertical tube type, and are rated at 425 H.P. each. The working pressure is 150 lbs. There are four groups of two boilers each, three of the groups being fitted with automatic chain grate stokers operated by small vertical engines in the basement. The grate equipment was supplied by the Illinois Stoker Co., Alton, Ill. The fourth group is hand fired, and when the planing mill is completed and in operation, will consume all shavings, sawdust and scrap lumber.

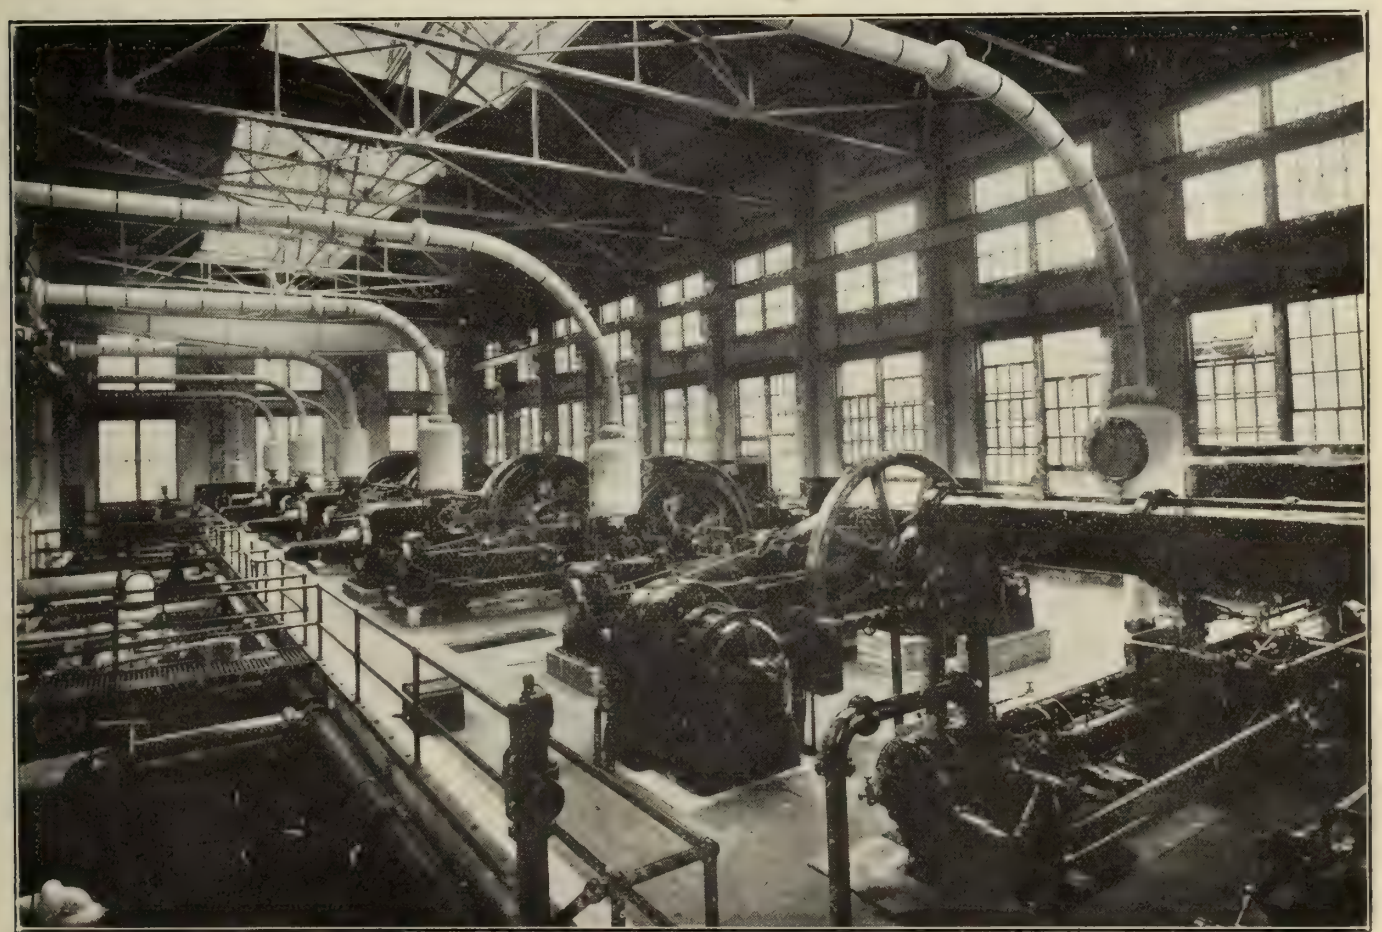
The boilers all blow off into a common blow-off main leading to a well situated outside the building and connected to sewer.

Chimney.

The products of combustion from all the furnaces pass into a steel breeching running overhead in a passage way between the back of the boilers and the fire wall previously mentioned. Natural draft is provided by a Weber reinforced concrete chimney, 210 feet high above ground level, by 11 feet internal diameter. The breeching enters the chimney about 12 feet above ground level by an opening 15 x 6 feet. The chimney has two 24 x 18 inch cleaning doors at the bottom, and stands upon a concrete footing 30 feet square at the base by 11 feet deep. This footing rests upon eighty-four wooden piles, 25 feet long.

Coal and Ash Handling Equipment.

The automatic system of handling coal and ash is very complete, and the labor necessary in the boiler house is reduced to a minimum. Coal is brought in from the west end of the yards in hopper cars, which are weighed on track scales before reaching the power house. The cars then proceed on a track adjacent to the boiler house and ascend a ramp elevated 7 feet above grade level. The coal is here dumped into a steel receiving bunker, from whence it is taken by a belt conveyor to the crusher, situated



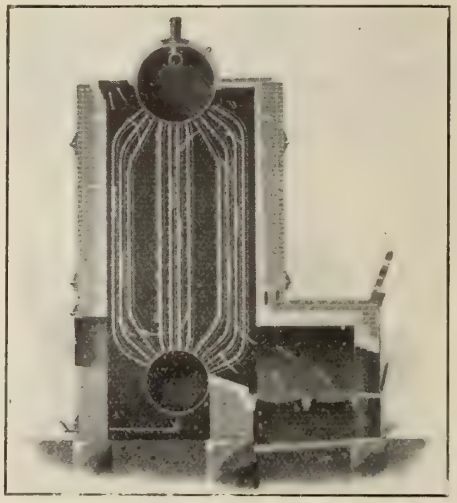
Interior of Power House looking west. In the foreground are seen the Inglis Air Compressor and the Motor-Generator Set.

in the boiler house basement. The crusher is driven by a 20 H.P. motor. The coal next passes to an endless chain bucket conveyor, driven by a 10 H.P. motor; and is carried to the overhead bins, of which there is one for each boiler. These bins are lined with fibricated asphalt supplied by the Interior Construction Co., Winnipeg. This consists of a mixture of asphalt, asbestos and sand, and it is expected to turn out an improvement on the usual concrete lining, which wears so rapidly under the weight and friction of the coal. From the overhead bins the coal descends by chutes to the stoker hoppers, so that from the time it is dumped from the cars to the time it reaches the grates it is handled entirely by automatic means.

The endless chain conveyor is also used for ash removal. Its horizontal run is, of course, in the basement, so that the ashes are merely raked out from the ash pits and discharge themselves through chutes to the conveyor, which elevates them in the same way as it does the coal, but is now tripped to deliver the ashes to a special concrete-lined ash hopper located overhead alongside the coal bins. From here the ashes pass by steel chutes to the cars outside, so that the same car which delivers coal may be used for removing ash, thus saving switching. The coal crusher and conveying apparatus was installed by the Jeffrey Manufacturing Co., Ltd., Montreal, and is of their latest type.

The Engine Room.

As above mentioned, the engine room is 150 feet long by 60 feet wide, the head room to the underside of the steel roof trusses being 30 feet. The walls for a height of 6 feet from the floor are finished with a coat of black paint; above this height they are whitewashed. The floor consists of standard maple flooring laid on top of a rough lumber under-floor, which in turn is laid on 4 x 6 inch timbers bedded in bituminous concrete. Ample lighting is secured by windows in the side and end walls, and by central skylights in the roof. The engine room is served by a



SECTION SHOWING CONSTRUCTION OF ERIE CITY VERTICAL WATER TUBE BOILER.

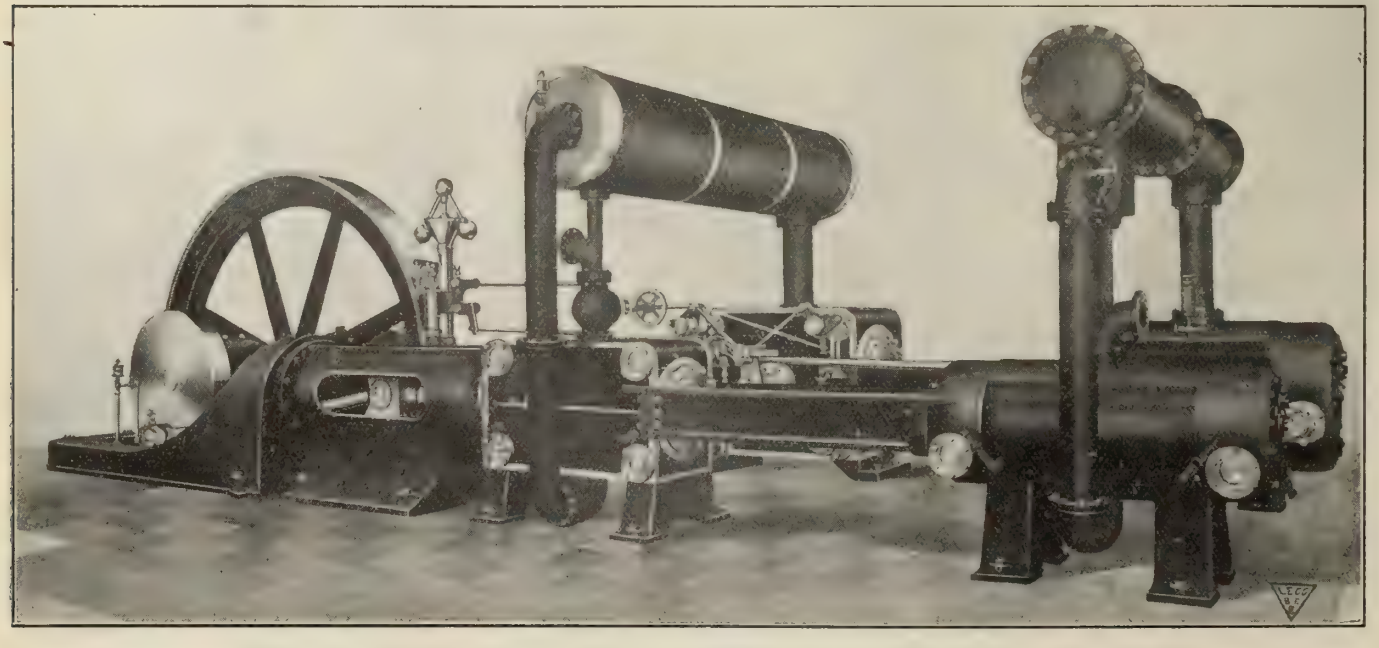
hand-operated 10-ton travelling crane supplied by Geo. Anderson & Co., Ltd., Montreal.

All the generators are by the Canadian General Electric Co., and all the engines are by the Goldie & McCulloch Co., the nominal capacity of the plant being 2,050 kilowatts. There are three main units, each consisting of a cross-compound Corliss engine direct connected to a 3-phase generator of 500 K.W. capacity. These three engines have cylinders 21 and 34 inches in diameter by 30 inches stroke, and run at 150 R.P.M. A fourth A.C. unit consists of a 250 K.W. generator driven direct by an 18 x 30-inch simple Corliss engine running at 150 R.P.M. All alternating current is 3-phase, and is generated at 600 volts, 60 cycles.

Duplicate exciter units for the four A.C. generators are located at the west end of the engine room, and consist of two Ideal high-speed engines (11 x 12-inch), running at 275 R.P.M., and direct coupled to continuous current, 125 volt generators of 65 K.W. capacity each. To supply current for the variable speed motors driving many of the larger machine tools there are two D.C. units. One of these consists of a 14 x 30-inch simple Corliss engine running at 150 R.P.M., direct connected to a continuous current generator of 150 K.W. capacity. The second unit is a motor generator set; a 225 H.P. induction motor takes current from the A.C. bus bar, and drives the generator at 900 R.P.M. The capacity of both units is the same —150 K.W., the current being generated at 250 volts.

At the east end of the engine room is installed the main air compressor unit. This was supplied by the John Inglis Co., and is a horizontal cross compound Corliss two-stage compressor, having a capacity of 1,600 cubic feet of free air per minute against a pressure of 80-120 lbs. per square inch.

The steam cylinders are 16 and 25 inches, and the air cylinders 24 and 14 inches in diameter, the common stroke being 36 inches. Both air cylinders are fitted with Corliss inlet valves and poppet outlet valves. The engine has double wristplate long range cut off on the low

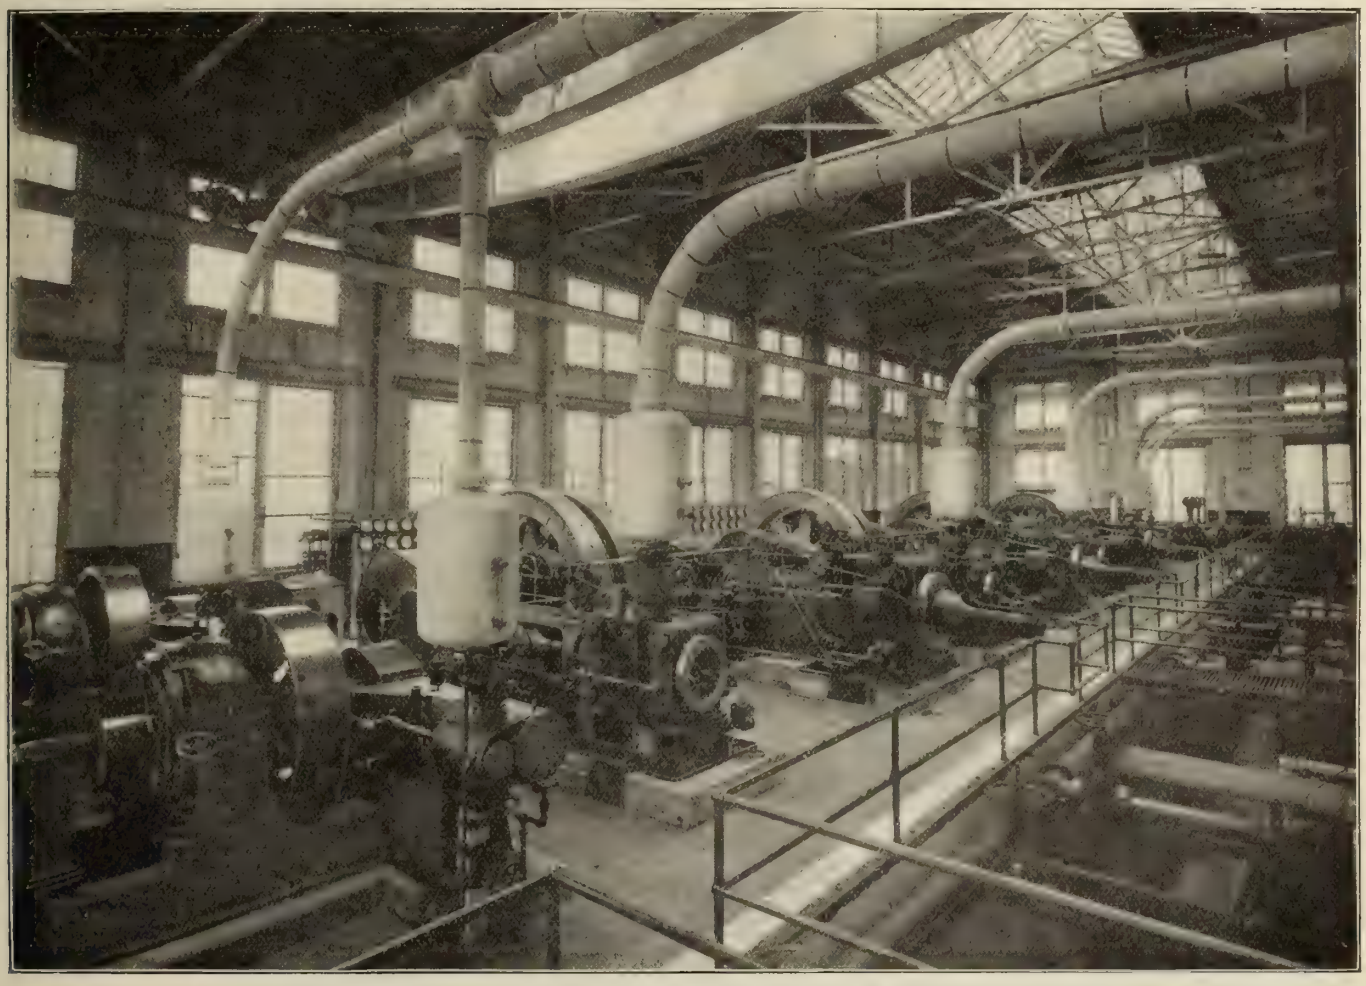


Horizontal Cross Compound Two-Stage Air Compressor, by the John Inglis Co., Ltd., Toronto.

pressure steam cylinder and single wrist plate on the high pressure. Speed is regulated by a combination centrifugal and pressure governor, pressure being taken from the discharge of the high pressure air cylinder and working an oil packed plunger on the governor. Both air cylinders and heads are water cooled, as is also the intercooler between the two cylinders. Steam passes from the H.P. to the L.P. steam cylinder through a reheating receiver standing above the cylinders, and heated by live steam. The engine runs non-condensing, and was designed for a speed of 90 R.P.M.

The pump pit runs the full length of the engine room at the foot of the dividing wall, the bottom of the pit being 9 feet below the level of the engine room floor. It is provided with a 6-inch auxiliary steam header running the full length of the pit, and connected with the main header by two 6-inch vertical legs provided with separators. This auxiliary header of course supplies steam to various pump units in the pit. The main steam header also carries a 10-inch vertical leg connecting to the line which provides steam for the hammers in the forge shop, for driving the fan

Before dealing with the feed pumps it may be as well to trace the course of the feed water on its way to the heater. The source of supply for the service water throughout the plant is a 2,000,000 gallon reservoir situated about 500 feet distant from the power house. From this reservoir the water is pumped up to a steel water tower, the bottom of which is 125 feet above grade level. This tower has a capacity of 100,000 gallons, and is supported by four steel legs resting on concrete piers. The two pump sets which raise the water to the tower were supplied by the John



Interior of Power House looking east. The two exciter units are seen in the foreground on the left of the illustration.

Pump Pit and Piping.

The wall dividing the engine room from the boiler house carries the main steam header on standard brackets. The header is of wrought steel, 12 inches in diameter, and has the branches riveted on. It is carried on the engine room side of the partition wall, and is connected to the boilers by 8-inch double bends. Steam pipes from the header to each engine have bends of large radius. The pipes to the Inglis air compressor and the two exciter engines are 4½ inch diameter, the other four engines having 7-inch pipes. All are provided with Crane separators.

engines of the indirect heating system and for heating those shops which use direct radiation.

The exhaust header is 18 inches in diameter, and, like the steam headers, extends the full length of the pump pit. All engines and pumps exhaust into this, part of the steam afterwards passing through a Hoppes open heater and part being used in winter for the indirect heating system in the various shops. From the heater the exhaust passes up a 16-inch galvanized steel stack to the atmosphere. The heater can of course be cut out when necessary for cleaning or repairs.

McDougall Caledonian Iron Works Co., Ltd., Montreal. They are located in the power house pump pit, and consist of duplicate 8-inch single stage horizontal turbine pumps, with extended bases. Each pump is direct connected on the same base with an 18-inch six-stage 70 H.P. horizontal Kerr steam turbine running at 1,500 R.P.M. The capacity of each set is 1,200 U.S. gallons per minute, against a head of 150 feet. From the tower the water passes to the main service pipe, and is thence distributed throughout the shops. The connection from the service pipe to the feed water heater is fitted with a reducing valve,

which brings the pressure down to about 5 lbs. per square inch.

From the heater the feed passes to two 14-10¼-10 Blake horizontal duplex piston pattern boiler feed pumps mounted on cast iron bed plates. Each of these pumps has a capacity of 200 U.S. gallons per minute against the boiler pressure of 150 lbs. They are cross connected in such a way that they may draw either from the reservoir, the service line or the heater; and their delivery is cross connected to the two feed lines, so that all danger of breakdown is practically eliminated.

Protection against fire is provided by two Underwriter duplex fire pumps built by the John Inglis Co. The combined capacity of the two pumps is 2,000 gallons per minute against a pressure of 200 lbs. per square inch. Two Marsh steam-driven vacuum pumps deliver the heating returns to the feed-water heater, and a small Canton-Hughes pump takes care of the engine and separator drips, delivering same to the heater or to sewer, as desired.

No provision has as yet been made for softening the water; though it is probable that it will be found necessary to treat the boiler feed at least, if not the whole supply, since the water is very hard. It is pumped from the Red River to the 2,000,000 gallon reservoir, as will be presently described.

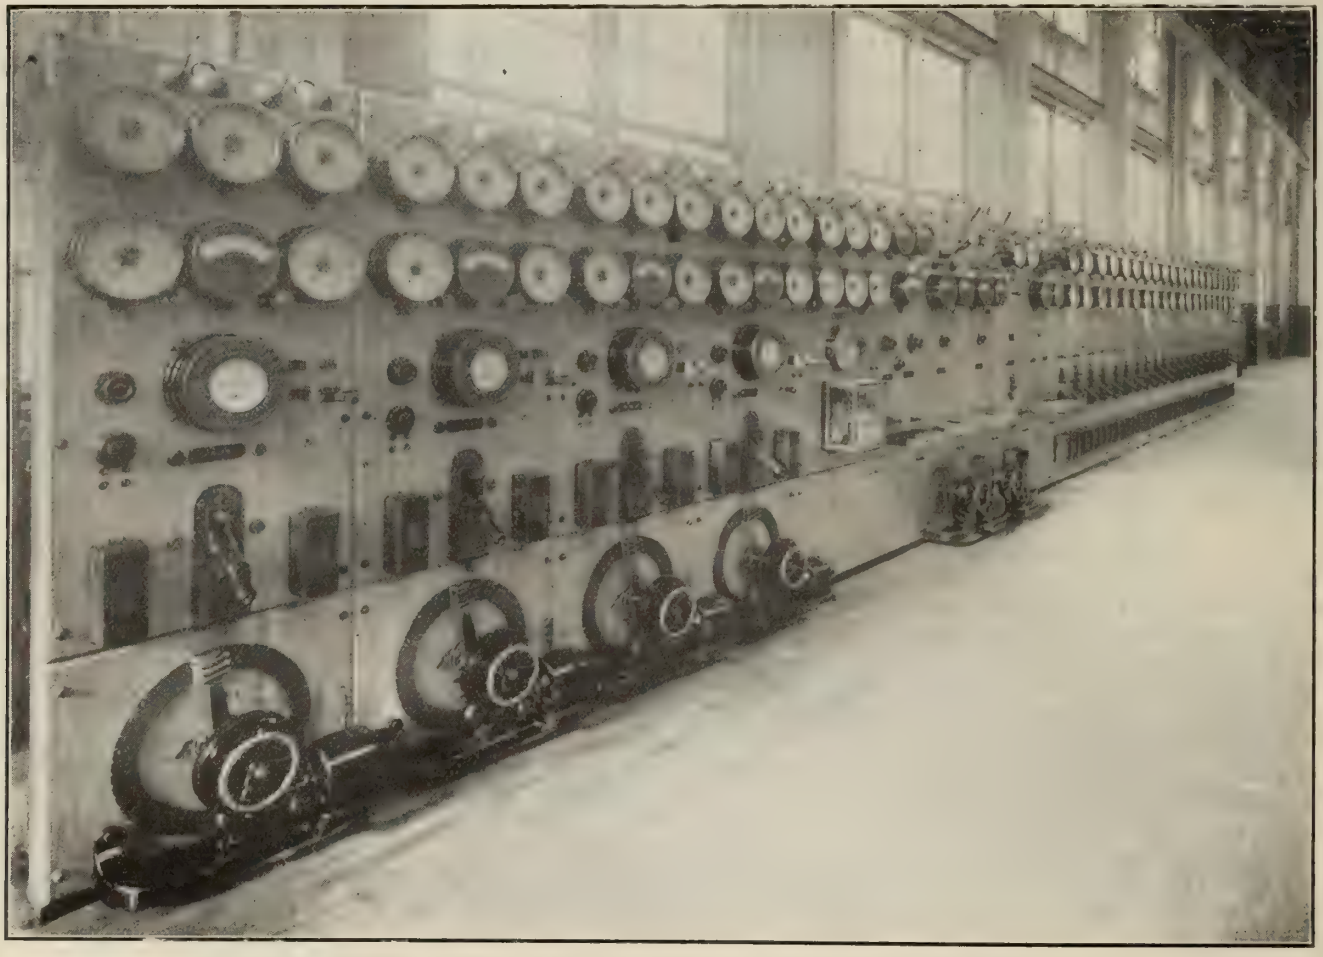
At the west end of the pump pit in the power house there is a 6-inch artesian well, 180 feet deep. A 4¼-3-36 Blake vertical deep well pump draws 40 gallons per minute from this well, and delivers it to a 10,000 gallon tank suspended below the main tank of the water tower From here it flows to the various drinking fountains throughout the shops, the Red River water being unsuitable for drinking purposes.

All valves and fittings on the steam, exhaust and water lines are of Jenkins or Crane make, the valves on the main steam lines being fitted with by-pass valves. The high and low pressure steam piping throughout the plant is thoroughly and neatly lagged with an efficient non-conducting material, and presents a very pleasing appearance. The various pipe lines are painted with distinctive colors to render their identification at all times easy. Thus the high pressure steam lines are colored white; low pressure steam, buff; heating returns, blue; compressed air lines, green; fire service, red; hydraulic pressure, brown; and general water service pipes, black.

The cylinders of the four Goldie & McCulloch engines are lubricated by Richardson automatic sight-feed oil pumps driven from the valve gear; while the Inglis air compressor is fitted with a Detroit sight-feed lubricator. All bearings are lubricated by the continuous gravity system, the oil flowing from an elevated tank to the various bearings, and from thence to a Burt unit type oil filter in the pump pit. From the filter a small steam pump elevates it once more to the tank.

The Switchboard.

The switchboard was manufactured and installed by the Canadian Westinghouse Co., Ltd. It is composed of twenty-one panels of blue Vermont marble, having a total length of 52 feet and a height of 7 feet 8 inches. There are nine generator panels, the remainder controlling the various A.C. and D.C. feeders. The A.C. generator panels are equipped with an oil circuit breaker with inverse time limit relays, ammeters, voltmeters, indicating wattmeter, field ammeter and watt-hour meter. The rheostats for both A.C. and D.C. generators are electrically operated and have faceplates mounted on the sub-panels of the board. The total-load panel for the A.C. generators is equipped with ammeters, voltmeter, power factor meter and graphic recording



THE POWER HOUSE SWITCH BOARD, BY THE CANADIAN WESTINGHOUSE CO., LTD.

wattmeter. All the A.C. feeders are controlled by oil circuit breakers with inverse time limit relays, and have an ammeter and indicating wattmeter in each circuit, two feeders being mounted on one panel. The D.C. generator panels have carbon-break circuit breakers, ammeters, voltmeters and knife switches. The two D.C. feeder panels are also equipped with carbon-break circuit breakers.

All A.C. meters on the board are Westinghouse type "F," the D.C. meters, type "FL," and the oil circuit breakers, type "B." A Westinghouse synchroscope is supported on a swinging bracket at one end of the board. Each panel has an engraved name plate, and the general finish of the meters and circuit breakers is polished copper on a black background, so that the board presents a very handsome appearance.

The Reservoir.

As already mentioned, the water supply for the plant is obtained from a 2,000,000 gallon reservoir, which is filled by a pumping plant situated on the banks of the Red River some 6 miles distant. The reservoir is of concrete, and is 270 feet long by 60 feet wide, the bottom being 21 feet below ground level. It is divided longitudinally into two tanks by a central wall of reinforced concrete, resting on a footing of similar material. This central wall enables one-half of the reservoir to be cleaned out while the other half is in use.

The side and end walls are of plain concrete, as are also their footings. The central wall is 30 feet high, while the side walls are 25 feet in order to give sufficient slope to the roof. The latter consists of two thicknesses of 2-inch tongued and grooved planking resting on steel girders and purlins, and is covered with 4-ply waterproof roofing.

Flooding is provided against by a 12-inch cast-iron overflow pipe connected to sewer. Access to the interior of the reservoir is had by means of four hatches in the roof, iron ladders extending to the bottom of the tanks. The interior is wired for electric lighting, and heat is provided in winter by pipe coils taking steam from the low pressure line.

The pumping station on the banks of the Red River, from which the 2,000,000 gallon reservoir is filled, contains a producer gas driven plant consisting of two complete units in duplicate. Each unit comprises producer, scrubber and 60 H.P. single cylinder gas engine driving a vertical triplex force pump fitted with extra large suction and delivery valves, which are readily accessible. Each pump has a capacity of 40,000 gallons per hour, against a head of 50 feet. The suction lines run out into deep water and are 14 inches in diameter, the delivery line being 12 inches. The engines are cross connected with the two producers, and the pumps are cross connected with the two suction lines. This installation was supplied by T. H. & J. Daniels, Ltd., Stroud, England.

Carpenter Shop, Pattern Shop and Grey Iron Foundry

The relationship between the pattern shop and the grey iron foundry in every plant being so intimate, these two departments, together with the locomotive carpenters' shop, are here described in one article. All three are admirably equipped, the foundry in particlar being well worthy of attention.

THE locomotive carpenter and pattern shops are accommodated in one building, numbered 6 on the view given on page 188. It is a steel framed, two storey structure, 100 feet long by 70 feet wide, and as may be seen, is adjacent to the foundry. The building has been constructed to be practically impervious to the attacks of fire from the outside, and precautions have been taken to prevent any fire, starting inside the building on the ground floor, from reaching the upper floor, which is used for pattern storage.

The lower floor, as above stated, is occupied by two departments; the carpenters occupying the front of the shop and the pattern-makers the rear half. An industrial track runs from the centre of the floor, with turntables and branch tracks to the grey iron foundry and stores platform. The toilet and locker rooms are on the north side, and are equipped with porcelain basins, etc., and steel lockers with expanded metal doors, similar in all respects to those in the other shops. Two lines of shafting run the full width of the shop to drive the machines for each department. Each line shaft is belted to a 25 H.P. motor. The shop is heated by the indirect system of radiation, and the lower floor is of 3-inch planks spiked to 4 x 6-inch timbers bedded in bituminous concrete, as in most of the other shops. A list of the mechanical equipment is given in the accompanying table:—

CARPENTERS' DEPARTMENT.

	Machine.	Maker.
1	Planer, moulder and matcher	Berlin Machine Works.
1	Cut-off saw	Berlin Machine Works.
1	Band saw	Canada Machinery Corporation.
1	Swing cut-off saw	Canada Machinery Corporation.
1	Tenoning machine	Canada Machinery Corporation.
1	24-inch planer	Canada Machinery Corporation.
1	2-spindle shaper	Canada Machinery Corporation.
1	Woodworker's lathe	Fay & Scott.
1	3-spindle boring machine	Greenlee Bros.
1	Wood trimmer	Oliver.
2	2½-inch woodworking air drills	Cleveland Pneumatic Tool Co.
1	Combined grindstone and revolving oil stone	Mummert, Wolf & Dixon.

PATTERNMAKERS' DEPARTMENT.

2	Patternmakers' lathes	Fay & Scott.
2	Band saws	Canada Machinery Corporation.
1	2-spindle shaper	Canada Machinery Corporation.
1	24-inch planer	Canada Machinery Corporation.
1	Face lathe	Canada Machinery Corporation.
1	Wood trimmer	Oliver.
1	Knife grinder	Fay and Egan.
1	Universal saw bench	Fay and Egan.
1	Combined grindstone and revolving oil stone	Mummert, Wolf & Dixon.

The usual work benches, glue pots, hand screw clamps, etc., are also provided, and the shop is excellently laid out for its intended work.

Pattern Storage.

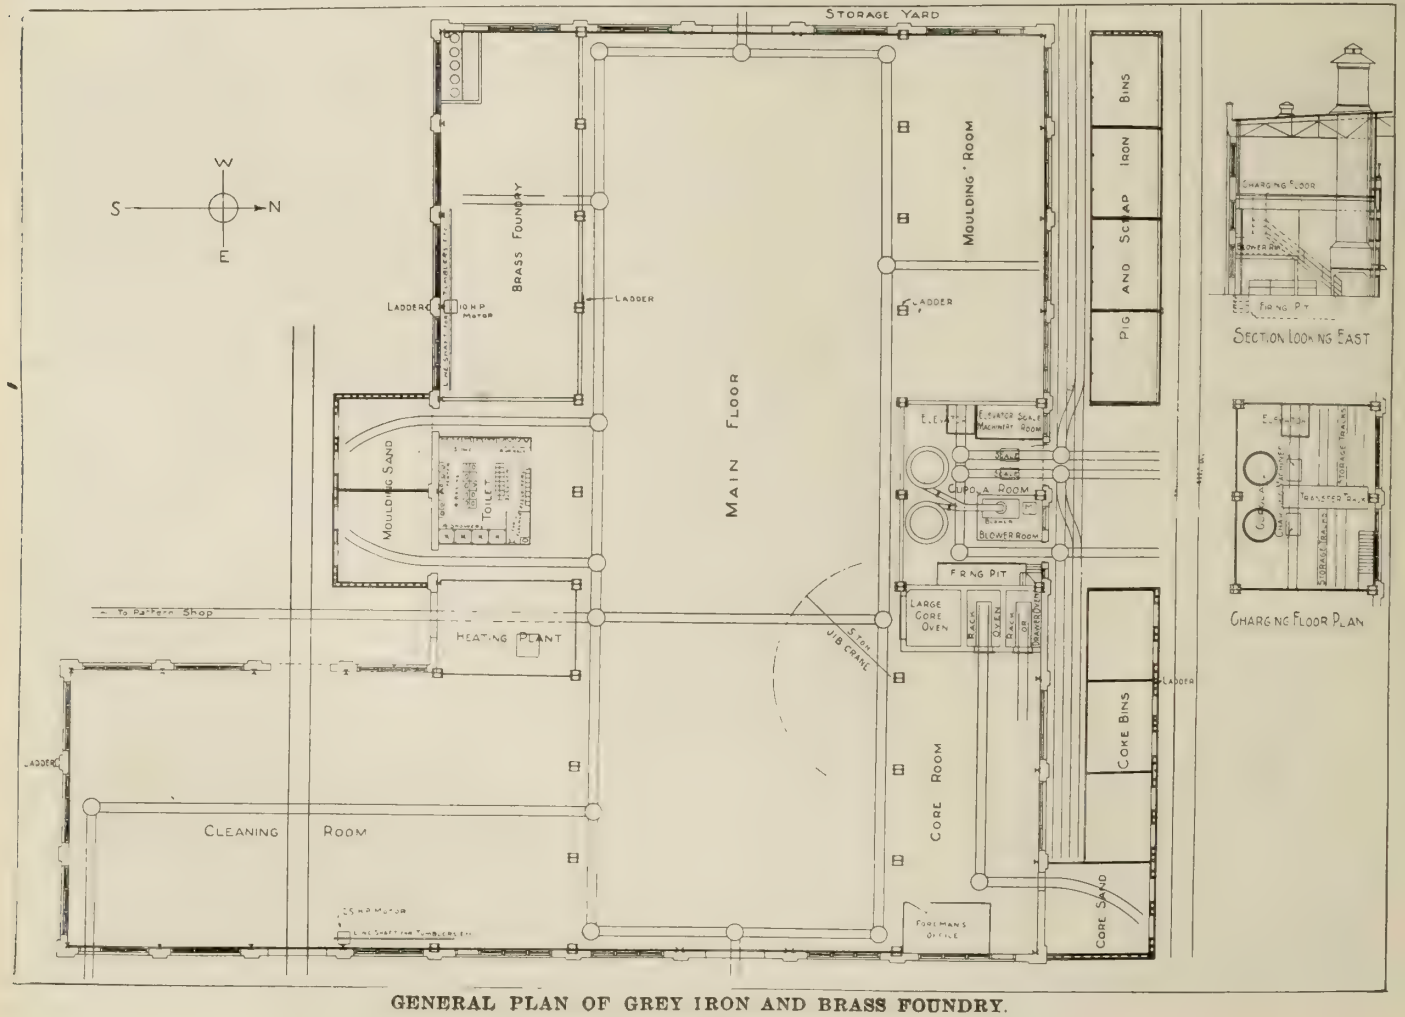
Patterns are stored in the upper section, which has a concrete floor supported on square concrete pillars. Metal shelves and racks for carrying the patterns extend to a height of about 12 ft., access to the upper ones being had from steel gratings, reached by steps and running along the front of the shelves about 6 feet above floor level. The rear part of the room is not equipped with shelves, being intended for storage of the larger patterns such as cylinders, wheel centres, smoke stacks, etc. Instead of the usual plug sockets and extension cables, numerous drop lights provide

artificial illumination. The pattern store is reached from the ground floor by an enclosed stairway fitted with fire doors, and heavy patterns are taken up by a hydraulic elevator running in an enclosed concrete shaft,also fitted with fire doors. In this way the risk of fire spreading to the pattern store from downstairs is reduced to a minimum. The elevator is operated by the shop water service pressure, equivalent to about 130 feet head.

Grey Iron Foundry.

This is probably one of the best equipped railroad foundries in the country, although not the largest. Not that it is by any means small, being 200 feet long by 130 feet wide, with a cleaning annex 60 feet by 80 feet. The building has a centre bay 70 feet wide and two side bays of 30 feet each. The plan on this page shows the general layout. The 70-foot bay forms the main moulding floor, and is served by a 15-ton electric traveling crane fitted with an auxiliary 5-ton hoist. The former lifts at 10 feet per minute and the latter at 30 feet, the traveling speed being 200 feet per minute. This crane was built by J. Booth & Bros., Rodley, Leeds, England, and is similar to those in the machine shop. The main bay is further served by an industrial track running around it, and by light bracket cranes affixed to the columns. Cylinders and other large castings are made at the lower end of the main bay, i.e., east of where the industrial track crosses the floor. Attached to the column nearest to the core oven is a 5-ton electric jib crane for handling the larger cores between the oven and the moulds. This crane was supplied by Geo. Anderson & Co., Montreal, and is fitted with a small elevated platform, on which is placed the controller, etc. This gives the operator a clear view all round, and enables him to handle the cores better when lowering them into the moulds. The crane is equipped with a 12 h.p. alternating current motor, built by the Lancashire Dynamo & Motor Co., and serves the cylinder floor only. It has a radius of 25 feet.

The north 30 ft. bay is divided into two parts by the cupola room and core ovens, which are centrally located to serve the whole foundry. The west half is used for moulding small work, and the east half forms the core room. Both sections are served by a 1-ton hand operated traveler, built by Geo. Anderson & Co. The core room is fully equipped with benches, shelves, etc., and an industrial track runs up the centre, terminating in one of the core ovens. The latter are three in number, all constructed by F. Hyde & Co., Montreal. The largest oven faces the main floor and is used for cylinder and other large cores. It measures 12 ft. x 12 ft. x 9 ft. and has racks on all three walls; heavy cores are run in on a truck. The other two core ovens are for general cores, and have racks and shelves on the north side and end wall only. The firing pit for all three ovens is located in the cupola room. The latter measures 30 x 40 ft. and contains two Whiting cupolas, a No. 7 and No. 9, having capacities of 11 tons and 16 tons per hour respectively. Pig, scrap and coke are brought in by industrial tracks from the bins outside, the trucks passing over track scales on their way to the 2-ton pneumatic elevator which raises them to the charging floor. The latter is of steel plate, laid out with storage tracks which are served by a small transfer table. In this way, a dozen or more loaded trucks can be stored ready for use. Each cupola is served by a Whiting pneumatic charging machine. Blast at 14 oz. pressure is supplied by a Sturtevant No. 11 blower (positive type) direct driven by a 50 h.p. Bruce Peebles A.C. motor. The blower outfit is enclosed in a 15 x 10 ft. room on an



GENERAL PLAN OF GREY IRON AND BRASS FOUNDRY.

elevated platform below the charging floor. Below this platform is a 36 in. x 60 in. cinder mill driven through gearing by a 5 h.p. motor.

Brass Foundry.

On the south side of the building there is a fully equipped brass foundry, measuring 80 ft. by 30 ft. This is an entirely self-contained little shop, making and drying its own cores, for which purpose it is equipped with a Hill & Griffith portable core oven. In the south-west corner there are four coke-fired brass furnaces, blast for which is supplied by a Canadian Buffalo Forge Co. 24-inch belt driven blower. The shop is served by a 1 ton hand traveler, and there is a line shaft along the wall driven by a 10 H.P. Bruce Peebles motor. This drives the blower, wet and dry tumblers, band saw, sprue cutter and double emery grinder. In the middle of the south bay stand the toilet and locker rooms. The lavatory arrangements here are very complete and include four shower baths in addition to the usual wash basins. The foundry is heated by the indirect system of radiation, the fan and heater coils being placed on an elevated platform near the toilet rooms.

Most of the moulding is straight hand-work, but grate bars and other suitable patterns are moulded on a No. 2 Buch's gravity moulding machine, driven by a 10 H.P. motor. There is also a brake shoe moulding machine by F. Hyde & Co. Further equipment includes hand ladles ranging from 60 lbs. to 250 lbs., three truck ladles of 1,500 lbs. capacity, and three heavy geared ladles having capacities of 4,000 lbs., 10,000 lbs., and 20,000 lbs., respectively. The smaller flasks are of wood and the larger of cast-iron. The core room is provided with four benches, Hammer core machine, core wire straightener and all necessary equipment.

Cleaning Room.

The cleaning annex at the south-east corner, is at right angles to the main floor. It is 80 ft. long by 60 ft. wide and, like the rest of the shop, is extremely well equipped. A 5-ton electric traveling crane by Geo. Anderson & Co., Montreal, serves the whole floor. Castings can thus be loaded direct on to cars; a standard gauge track running into the annex. There is also an industrial track leading via the midway to all other departments. A 25 H.P. motor drives a line shaft against the east wall, where are placed the grinding wheels, tumbling barrels, etc. The latter are all fitted with dust hoods and exhausters.

Pig, Coke and Sand Storage.

The pig, scrap, coke and core sand are stored in bins arranged in a long covered-in shed to the north of the building. This is divided into bins, which are filled from the cars on the adjacent standard gauge track. Between the bins and the foundry wall are the industrial tracks by means of which the pig, scrap and coke are taken to the weigh-scales and elevator. Thus, to obtain raw material it is never necessary to go out into the open air—a great advantage in severe winter weather. Moulding sand is stored in bins on the south side, behind the toilet rooms. These bins are also filled from cars on the adjacent track.

The foundry is, of course, piped for compressed air for the use of the chipping hammers in the cleaning room and for sand rammers, etc., on the main floor.

It will be seen from the above that the Grand Trunk Pacific Railway will have a very fine foundry at their disposal. If any fault can be found it perhaps lies in the size of the cupola room, which in the writer's opinion is too small. As previously mentioned it measures only 40 ft. by 30 ft., and while this does not cramp the charging floor appreciably, it results in a very crowded ground floor. As may be seen from the plan, the elevator, track turntables and weigh scales are, one would think, too close to the cupolas, to escape rapid deterioration from the heat, cinders, etc., which are inevitable accompaniments of dropping the bottom at the end of the cast. The elevator, while very conveniently placed as regards the charging floor, is too near the right-hand cupola to allow the slag to be conveniently removed; the slag holes being inside the cupola room and on the sides of the cupolas. However, when the foundry goes into operation, these fears may prove groundless.

Store House, Oil House, Offices, Sewage Pump House, Etc.

What may be called the minor departments have been given the same careful attention as the larger and more important buildings. The oil house is well isolated from the storehouse and yet is not so far away as to be inconvenient.

THE storehouse stands at the south end of the midway on the west side. It consists of a white brick building with a roof of reinforced concrete supported by pillars of similar material. The probability of having to add a second storey at some future time has been kept in mind in designing this roof. As is usual, the building stands upon a platform 4 feet above rail level to facilitate the handling of material to and from cars on the adjacent tracks. This platform is of reinforced concrete and extends all round the building; its front edge extending several feet into the midway to enable the electric traveler to handle material from it. Ramps at this end lead down to the midway level. The building, which measures 260 feet by 60 feet, is fitted up with the usual storehouse racks, shelves and bins, and has three doors on each side, giving access to the loading platform. As in the shops, hose reels are affixed to the walls at frequent intervals as a protection against fire, chemical extinguishers being also provided. The concrete floor has a coating of cement to give a smooth finish. The head storekeeper and his clerical staff are accommodated in the front portion of the building, which forms a handsome and comfortable office with hardwood floor.

The storehouse is heated by direct radiation, and lighted by 220 volt incandescent lamps. The platform is illuminated at night in the same way; the lamps being arranged over the storehouse windows in clusters of five with enamelled iron reflectors.

Stores Platform.

This building is numbered 10 on page 188, and forms an adjunct to the storehouse, from which it is divided by two tracks. Here is stored the heavier material, such as needs a crane to handle; the building being equipped with a 5-ton hand operated traveler built by Geo. Anderson & Co. As in the case of the storehouse, the stores platform, which is 180 feet long by 58 feet wide, stands 4 feet above rail level, and projects out into the midway sufficiently far to be served by the midway crane. The structure on the platform is a light steel frame covered in with corrugated sheeting and a roof of tarred felt. There are two double doors on each side and one at each end. The runway for the crane extends out to the front of the platform; special doors being fitted to allow it to pass out of the building. In this way, loads can be transferred to or received from the midway crane. The platform and shed

are lighted by incandescent lamps similarly to the storehouse.

The Oil House.

The various kinds of oil used, with the exception of crude oil for fuel purposes, are stored in an oil house, situated some distance to the rear of the storehouse. It is surrounded by a concrete unloading platform at the same level above rail as the storehouse platform, with which it is connected by a gangway. The oil house consists of a small brick building, 30 feet by 40 feet, with a concrete basement in which are placed nine horizontal cylindrical steel tanks for the storage of the different varieties of oil. These are arranged to be filled by gravity from tank cars, or from barrels through openings in the platform, as may be desired. There is a hydraulic elevator, operated by the ordinary water service pressure, which handles barrels, drums, etc., between the basement and platform.

The upper floor is divided into two rooms. The rear room is used for storage of tallow, cotton waste, etc., while the other contains Bowser self-measuring pumps for raising oil from the storage tanks below. Gasoline is stored in a tank buried underground, outside the building and pumped up in the same way. Direct radiation is used for heating this building.

Motive Power Offices.

The motive power administrative and clerical staff are accommodated in a brick building on the east side of the midway, opposite the stores platform. It measures 68 feet by 60 feet, and consists of two storeys and basement. The usual fireproof vault runs up the centre of the building with doors on each floor. In the basement are the lavatories and storage rooms and also a large laboratory for the engineer of tests. The ground floor is occupied by the timekeepers, accountants, etc.; while on the upper floor are the drawing office, blueprinting room. etc. The floors are of maple and the interior woodwork generally has a handsome appearance. The building is heated by direct radiation, and lighted by incandescent lamps.

Sewage Pump House.

A main sewer surrounds the plant, to which connections are made from the various shops. As there is not sufficient fall from the site to the Red River for a gravity flow, it has been found necessary to put in a pumping station to force the sewage to the river. The pump house is located 1,400 feet west of the storehouse, and is not seen on page 188, being outside the boundaries of the plan there shown. It is a concrete building, 31 feet by 28 feet inside, and rests on concrete foundations. Below the floor is a large sump, the bottom of which is some 25 feet below ground level. Into this the main 42-inch sewer discharges; the sewage being pumped thence to the Red River by two submerged pumps driven by direct connected vertical motors, located on the floor above. The larger of the two units is a 26-inch vertical centrifugal pump, having a capacity of 16,000 Imperial gallons per minute against a head of 48 feet. It is direct driven by a 350 h.p. 3 phase 60 cycle 550 volt motor, provided with a thrust bearing to take the weight of the rotor only. The smaller unit consists of an 8-inch vertical centrifugal pump direct driven by a 30 h.p. motor of the same type. This outfit was designed for a capacity of 2,000 Imperial gallons against a head of 15 feet. It will be in operation at all times, while the larger unit is intended to take care of storm waters, etc. The pumps are automatically started and stopped by means of floats, which operate the motors by means of two Cutler-Hammer automatic starting panels. Hand control is also provided for use when necessary. The switchboard is of blue Vermont marble and has a panel for each motor, in addition to the automatic starting panels. Current is brought from the power house by a lead and paper covered feeder, laid in a tile conduit. The 350 h.p. motor panel has the following equipment:—one 400 amp. 3-pole singe throw automatic oil switch: one 500 amp. Weston ammeter, and one 600 volt Weston voltmeter. The other panel has one 50 amp. automatic oil switch; one 60 amp. Weston ammeter, and one 600 volt Weston voltmeter.

The pumps were constructed by the John McDougall Caledonian Iron Works Co., Ltd., Montreal, and the motors by Allis-Chalmers-Bullock, Ltd., Montreal. The two pumps are connected to one discharge pipe, 42 inches diameter. This pipe, some 6 miles in length, is provided with necessary manholes, vents, etc.

The Locomotive Roundhouse.

The 24-stall roundhouse at the south end of the midway has been in operation about 2 years, but really forms a unit in the Transcona plant since it will make use of the locomotive machine shop, having none of its own. The locomotive foreman will welcome the opening of the big shop, as he has decidedly been working under difficulties hitherto. The roundhouse is at present lighted by gas generated on the premises from gasoline. However, electric lighting will shortly be installed, current being taken from the works powerhouse, which will also probably supply compressed air. The latter commodity is at present delivered by two 11-inch Westinghouse compressors. Heating is both by direct and indirect radiation, the former supplementing the latter in very severe weather. Steam is generated in two return tubular boilers, built by E. Leonard & Sons, London, Ont.

The turntable is operated by an air motor, and when once it has got "coupled up" to the main plant, the roundhouse will be thoroughly up-to-date in every way.

General Remarks.

A feature of the Transcona plant is the distribution of the various equipment items. The leading Canadian toolmakers are all strongly represented, while Great Britain and the United States have been able to successfully compete in many instances, noticeably in the crane equipment. With two or three exceptions, all the British machines, including the Booth cranes, were supplied through Mussens, Ltd., Montreal. Other supply houses who secured large orders include Williams & Wilson, Montreal; Rudel-Yeates Machinery Co., Montreal; The Canadian Fairbanks Co., Ltd., Montreal; The A. R. Williams Co., Toronto, and Joseph T. Ryerson & Son, Chicago. The detailed lists on this and previous pages, show the large number of machine tools supplied by the John Bertram Co., the Canada Machinery Corporation and R. McDougall Co. The numerous steel lockers throughout the plant were supplied by the Dennis Wire & Iron Works Co., Ltd., London, Ont. The pipe lagging in the powerhouse and elsewhere was done by the Winnipeg branch of the Philip Carey Co.

The contract for the supply and installation of the leather belting was secured by D. K. McLaren, Ltd., Montreal, and following firms supplied motors for the individual and group drives, cranes, blowers, etc. After each name is given the aggregate horsepower supplied:—Lancashire Dynamo and Motor Co., 930½ H.P.; Canadian Westinghouse Co., 907 H.P.; Allis-Chalmer-Bullock Co., 767 H.P.; Canadian General Electric Co., 335½ H.P.; General Electric Co., 60 H.P.; Crocker Wheeler Co., 31½ H.P.; Allis Chalmers Co., 31½ H.P.; Rhodes Motor Co., 10 H.P.; Electro-Dynamic Co., 7½ H.P.; Westinghouse Electric Co., 6 H.P.

Vol. VIII. JULY, 1912 No. 7

THE N.T.R. SHOPS, TRANSCONA.

THE National Transcontinental Railway Commission and the Grand Trunk Pacific are to be warmly congratulated upon the magnificent locomotive shops just completed at Transcona, and fully described in our present issue. Great credit is due to the N.T.R. officials responsible for the design and equipment; and also to the contractors, who have carried out the work in a most thorough and businesslike manner. The first concrete was poured just three years ago, and as only about two-thirds of the whole plant is as yet completed, it will be seen that ample time has been taken to do the work in a first-class manner. A good many difficulties, however, had to be contended with, as the shops are located at some little distance from Winnipeg, on an isolated site, subject to flooding every spring. The latter trouble has been overcome by covering the site with a heavy gravel fill, but the tales told us, when visiting the shops, of the trouble experienced by the contractors' superintendent, owing to the excavations filling up quicker than they could be pumped out, are more or less interesting and amusing, now that the trouble is past. The locomotive department and power house are ready to be turned over to the Grand Trunk Pacific Railway, and the steel framework of the freight-car shop and planing mill is erected; so that the whole plant may be expected to be in operation by the time the N.T.R. is completed from Moncton, N.B., to Winnipeg in the fall of 1913.

With regard to the machine tool equipment in these shops, Canadian and the United States makers are about equally represented, while Great Britain is not far behind. A study of the lists of tools given in our article will show, as is only to be expected, that the United States furnished for the most part lines that are not yet manufactured in Canada. In a few individual instances this is not so, but generally speaking it will be found to be the case. We have no definite information as to the amount of money spent on machinery in each of the three countries mentioned; but as fas as mere numbers go, the machines supplied by each are roughly in the following proportions:—U.S.A., 40 per cent.; Canada, 37 per cent.; and Great Britain, 23 per cent. This includes the cranes, which are nearly all of British manufacture.

Our country is developing so rapidly and has such an assured future before it, that we confidently look forward to the time when a large plant like that at Transcona can be completely fitted out with Canadian equipment.

OUR OUTPUT RATING.

A GOOD many years ago, it was our privilege to see and know something of a steam propelled barge, engaged in the coal-carying trade on a large inland fresh water lake. The crew consisted of one man, who acted in the combined capacity of owner, captain, deckhand, engineer and fireman. The barge was some 70 feet long, 14 feet beam, 6 feet molded depth, and drew about 3 feet of water, loaded. Her motive power consisted of a vertical boiler, single cylinder non-condensing engine (a puffing Billy) with a one-blade propeller. The steam pressure caried was 20 pounds per sq. inch. The propeller was not one-bladed by design, but became so by accident, and remained so by indifference and carelessness. Fifteen miles in sixteen hours was the rated speed of sarcastic humor.

We are apt to believe that modern equipments, methods, and operations, leave no room for the existence of such seemingly old time happenings. Without making a too literal application, are not individual experiences much in the nature of a "15 miles in 16 hours" rate? Is it not a fact that plant equipments are in operation that attain their purpose at a like rate, and may it not be true that methods of manufacture still flourish by which output, whole or part, is got by a one-blade propeller as it were; the original design and purposes having been side-tracked by carelessness and indifference Individually, we have each one, some blades fewer than we were designed for, or have chips off some of them. We have not attained to that prominence in our profession we had mapped out for ourselves, and have not as a consequence secured its cash equivalent. We reason that our personal equipment is all right, and point to want of encouragement, or in other words to adverse undercurrents and headwinds. Are we sure that our motive power is all it might be, and if so, are we delivering it with a full-blade propeller Are we putting our knowledge to telling practical use?

Knowledge is power, only if applied, and unless it is so, we are somewhat in the position of a boiler in which steam is generated for the purpose of blowing it off again at the safety valves. Unless we apply our knowledge effectively, we cannot expect to make satisfactory progress. This barge made little headway, due to the indifference of its owner in the matter of supplying the lost and broken propeller blades. Our indifferent showing may be in the half-hearted way we go about our duties; in the thoughtless handling of some emergency when we know better; or in the determined attitude of being content with doing as little as we can, for the little we happen to get.

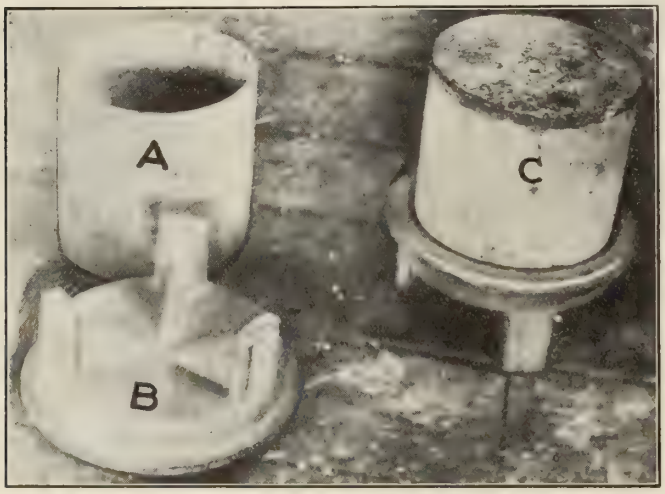
CASE-HARDENING BOXES FOR GEARS.

By Avery E. Granville.

WHEN case-hardening gears in square boxes, it is impossible to get them hardened evenly, as the heat is not the same in all parts of the box; so we have been using the type of box shown in the accompanying half-tone for nearly two years.

The box consists of a cast iron pot (A) and a base (B), with three legs on it; the combination appearing as at (C). In using this box, the pot is packed full of gears, and ground bone is packed in between the gear teeth and the outside of the pot; about ¾ inch of space being allowed for the purpose.



Case-Hardening Boxes for Gears.

The bottom is then inverted over the pot, and the whole thing turned over and set into the furnace.

The legs raise the box high enough for the heat to play under and around it, ensuring an even heat; and the size and shape of the box give the maximum result with the least waste of ground bone. As the patterns for a box of this kind are easily made, they can be produced in any size at a trifling cost. Another thing in their favor is that the crack can be easily fluted with fire clay if necessary, although as a rule the fit is so good that little gas can escape.

SIMPLE METHOD FOR CUTTING SQUARE-THREADED SCREWS.

By T. R.

CUTTING square threads in the lathe may be much simplified if performed in the following manner. Caliper the diameter of the bottom of the thread to be cut and grind a vee threading tool that will reach to the bottom and just clear the width of the space between the tops of the teeth; then proceed to cut the thread as if it were a vee thread. When you reach the bottom diameter desired, change your tool for one of the proper width for the square thread and finish the job with this. It will be found that you save not only time, but breakages of the tool, especially if the thread is a small one and you have not a steady rest to help you; the reason being that by this method you practically only cut the sides down square to the bottom, whereas, if you start the job with a square tool you have to take light cuts only, and the dip of the tool leaves the job anything but perfect.

Just try it out, and you will never again dread the job of cutting a square thread.

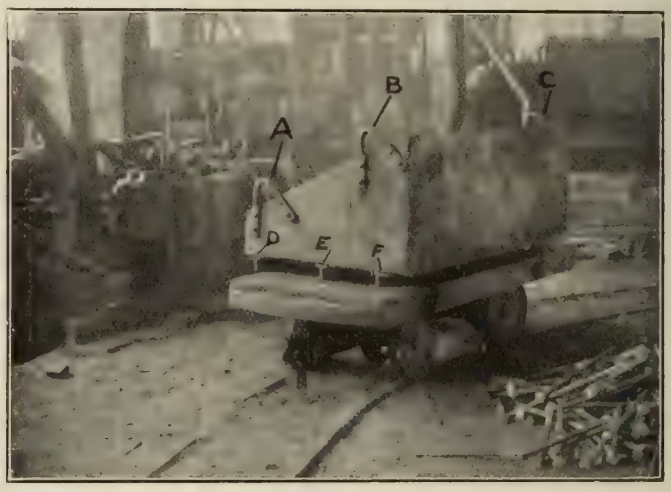
A CONVENIENT TOTE-BOX.

By Avery E. Granville.

IN our bolt shop we handle thousands of bolts a day, and in order to avoid unnecessary handling, we use the type of tote-box shown in the accompanying half-tone. These tote-boxes are made of heavy boiler iron and have strong eyes riveted to each end, as shown at (A), (B) and (C), the fourth one not being visible. These eyes are for the hooks of the crane chains, and are so placed that when the box is lifted it has no tendency to spill the contents.

At (D), (E) and (F) are three lengths of "T" iron riveted to the bottom, both for stiffness and to afford feet for the tote-box as it rests on the top of the small truck; a flat bottom having more of a tendency to let the box slip or skid around. The open side makes the box easy to load or unload, and in case it is wanted to dump the whole contents at once from the crane, all that is necessary is to slack away on the chains nearest the open side and the contents will slide out.

In using this box, a truck with a tote-box in place is run to the press where the long bars are cut into bolt lengths, and as fast as the pieces are cut off they are thrown into the box. When the box is full, the truck is run to the forging machine where the heads are made on the pieces. The bolts are then tossed into another box, which, when full, is run to the bolt cutter where the threading is done.



A Convenient Tote-Box.

The crane picks up the tote-box and carries it to the storage warehouse or to a car waiting for shipment.

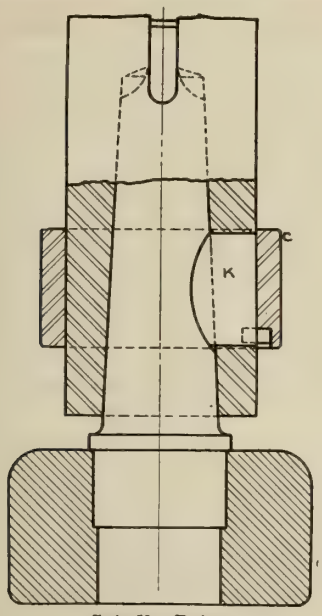
A SPINDLE DRIVE.

By D. O. Barrett.

WE experienced a great deal of trouble from breaking the tangs off the tapered shank of a tapping chuck which was used for large pipe taps. The body of the chuck was of cast iron with a square hole; all taps being supplied with a standard square. The steel shank was forced into this body, and in addition, four holes were drilled in the corners and pins driven in. The spindle of the drill press was removed and the tool steel key, K, fitted. At the bottom is a projecting pin which serves to retain the collar, C. This collar is placed

on the spindle before the chuck shank is inserted and then dropped down over. The key readily drops out when the shank is driven out in the usual manner by means of a tapered drift.

While on the subject of drill presses it seems that manufacturers overlook a



Spindle Drive.

seemingly insignificant but important point. The attachment of the counterweight chain to the sleeve on most of even the medium sized presses is by means of a ¼-inch eyebolt tapped into the end of the rack. Sooner or later this either breaks or pulls out, which usually necessitates tipping over the press in order to get at the chain. After several experiences of this kind we made a U bolt, wide enough to go over the side of the rack and riveted to it; the rivet extending entirely through. A little more attention paid to some of the minor details of machine tool design would be appreciated by those who have to operate the machines.

POSSIBILITIES OF FINE MEASUREMENT.

By J. Davies.

THE test room micrometer here shown uses two threads of different pitch in such a way that in one revolution of the spindle the measuring points of the micrometer will advance or recede in amount equal to the difference of the pitch of the two threads.

Referring to fig. 1, it will be seen that the spindle is threaded the standard 40 threads per inch, R.H., in the ordinary way, and for each revolution will advance

$$\frac{1}{40} \quad \text{or} \quad \frac{100}{4000}$$

inch. The other end of the same spindle is threaded

$$\frac{99}{4000}$$

inch pitch, R.H., and engages with an attached sleeve (D), which has a long supporting bearing inside the body of the micrometer. The outside of this sleeve has 25 fine longitudinal slots (not shown in the cut) to correspond with the 25 graduation marks on the measuring thimble, and in these slots the sliding key (C) engages. There are two lock nuts. Lock nut (A) locks the attached sleeve (D) to the spindle, so that the attachment does not interfere with the use of the micrometer in the ordinary way. Lock nut (B) locks the sleeve to the body of the micrometer to preserve the setting.

The method of operation is as follows: Use the micrometer in the ordinary way when measuring thousandths. To sub-divide

$$\frac{1}{1000}$$

measure to the nearest

$$\frac{1}{1000}$$

in the usual way; then push up the sliding key (C) to prevent rotation of the attached sleeve. Loosen lock nut (A) slightly—this will allow the measuring point to move in an opposite direction to that of the spindle and the actual opening or closing of the micrometer per revolution will be in amount equal to the difference in pitch of the two threads, or

$$\frac{100}{4000} - \frac{99}{4000} = \frac{1}{4000}$$

With the sliding key (C) raised, it will require four revolutions to record

$$\frac{1}{1000}$$

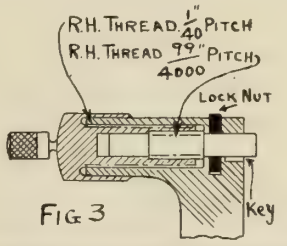
since one revolution equals

$$\frac{1}{4000}$$

consequently, each of the 25 graduations on the thimble will now record

$$\frac{1}{100{,}000}$$

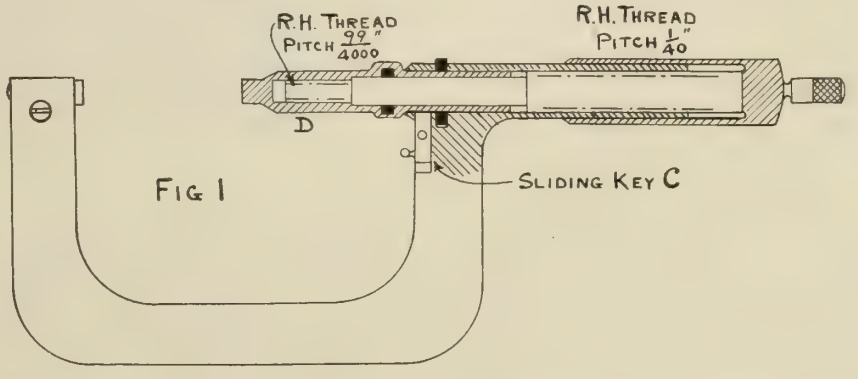
and the vertical lines that formerly represented tenths will now represent thousandths. With vernier graduations, as used on some micrometers, a reading of 1 millionth can be obtained. After completing the measurement, turn the micrometer back to the nearest thousand, lock the sleeve on the spindle, push down the

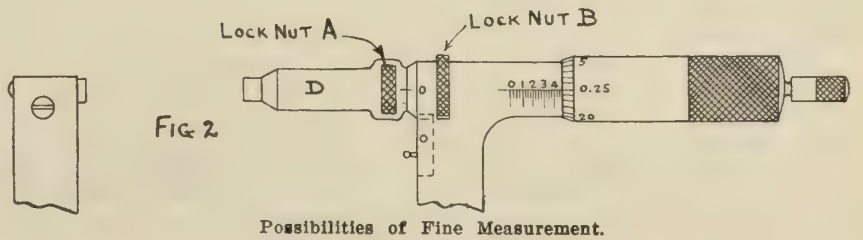


Possibilities of Fine Measurement.

sliding key and you have, again, the ordinary micrometer.

The same idea could be carried out by using the anvil end of the micrometer as shown in fig. 3. In this case, the twenty-five longitudinal slots would not be required and the sliding key would be replaced by a permanent one, as the attachment would be used for sub-dividing thousandths only. There would be no





Possibilities of Fine Measurement.

difficulty in cutting a thread having a pitch of

$$\frac{99}{4000}$$

inch, since it lends itself very readily to sub-division.

Take a lathe having a lead screw of ¼-inch pitch. The ratio of wheels is

$$\frac{99}{4000} \times \frac{4}{1} = \frac{396}{4000}$$

and the wheels required are

$$\frac{12\times33}{100\times40} \quad \text{or} \quad \frac{24\times33}{100\times80}$$

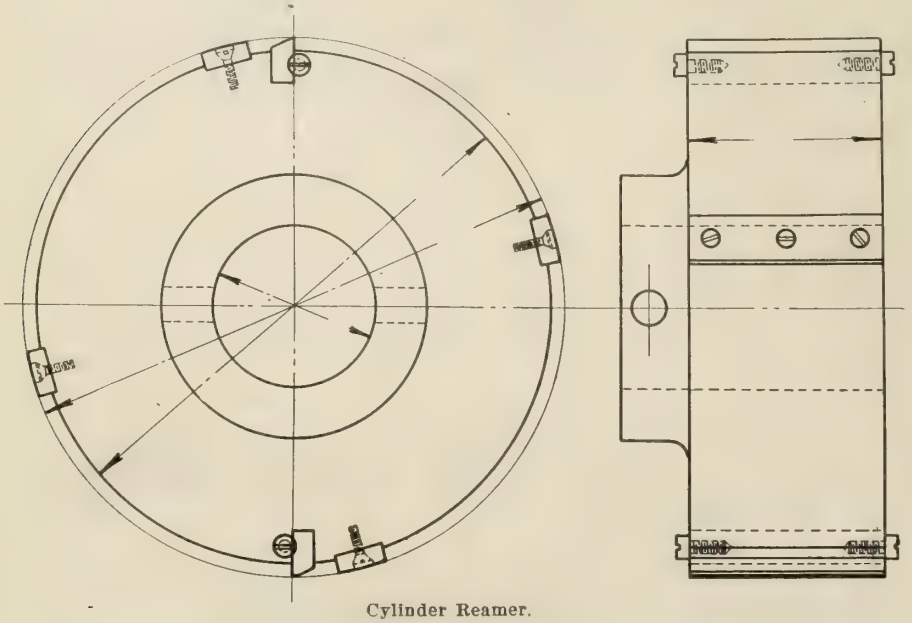
This micrometer is protected in Canada and the United States by J. Davies. Third Avenue, New Toronto, Ont., and is intended for the use of scientific instrument makers and others doing extremely fine work. Such refinements are, of course, unnecessary in the average tool room or machine shop.

A CYLINDER REAMER.

By D. O. Barrett.

THE reamer shown in the cut was designed to finish the cylinder of an engine which we were adding to our regular line, but wished to give a thorough tryout before finally going to the expense of purchasing tools for its manufacture.

The body is of cast iron; two inserted tooth cutters being provided of carbon steel, 7-16 by 15-16 inches, peened in, and further held by the screws at either end. Just back of, and also between the blades there are placed strips of red fibre held in place by countersunk machine screws. The fibre blocks were turned before the blades were finally ground, so that they were slightly larger than the reamer size. However, as they entered the cylinder, the sharp edge easily cut them to the proper size. Roughing and finishing reamers were provided, the former being .004 inch undersize. They produced an almost mirror finish, with a maximum variation either in rotundity or from end to end, of about .0003 inch. They seemed to be very free cutting, and the last reamer was made slightly loose on the bar and pin to give a floating effect. Of course, the fibre blocks would not last for long, as they cut considerably from the chips; but if these were kept blown out of the cylinder, the wear would be small, and in any case it would be a small job to replace them.



Cylinder Reamer.

INTERESTING LEGAL DECISION.

A LEGAL judgment of particular interest to contractors and engineers has been handed down in the Court of Review, recently, in Montreal, Que. The case arose over the collapse of a tank. The lower court had condemned the defendants to pay $9,590.68 damages on the grounds that the collapse of the tank on the building was due to the weakness and insufficiency of the walls, and that it was incumbent upon the defendants, as contractors, to assure themselves of this condition, before attempting to erect the superstructure and tank. The Court of Review whilst maintaining the damage award, holds that the collapse was due to a defect in the construction of the steel work supporting the tank. For this, the defendants were also responsible by reason of the fact that they had undertaken to carry out the work on the understanding that they would look after all details connected with such work.

LOCOMOTIVE WITH MECHANICAL STOKER.

A RECENT trip on an American locomotive equipped with a mechanical stoker resulted in the capability of the latter to maintain steam pressure over a long and difficult section of line being amply proved. According to a short account of the test which appears in the Railway Gazette, the engine was of the 2-8-0 or consolidation type, and the distance covered 137 miles. The train consisted of twenty-two loaded wagons weighing 906 tons. The line rises on a gradient of 10.6 feet per mile for about five miles, the next three miles is 26.4 feet to the mile, and for the succeeding five miles it is 60.6 feet per mile. In addition to these gradients there are others of a similar description, and during the whole of the climb up these hills the driver paid no attention whatever to the steam so far as the application of the injector was concerned. One injector was started and worked without being shut off for a distance of twenty-eight miles, requiring 1 hour 40 minutes to cover.

In the meantime, one injector was sufficient to maintain the water supply while the engine was working so heavily and the second ejector was started and worked as occasion demanded. This was done seven times in the period mentioned, the time of operation ranging from one minute to four minutes each. In no case was there any diminution of steam pressure, and on several occasions the second injector was put on solely to prevent the safety valve from lifting. The stoker was started and stopped thirty-one times on the trip, its period of continuous action varying from one to eighty-three minutes. On the easy and undulating portions of the road the stoppages were quite frequent.

BRASS MELTING FURNACES.

THE United States Bureau of Mines will make an investigation of brass melting furnaces with a view to ultimately reducing the oxidisation or volatilization losses of metal. A committee of the American Institute of Metals is co-operating with the Bureau of Mines and the members of this organization are requested to furnish detailed information covering the operations of their brass melting furnaces. The data sought include the shape and dimensions of furnaces, details of fuel and air supply, metal charges, percentages of losses, etc.

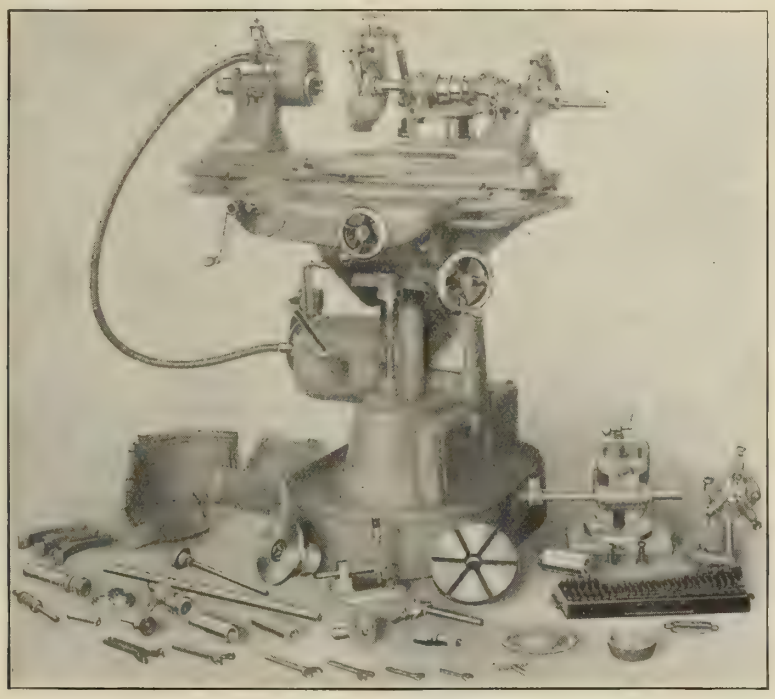
Mr. Rudolph Kauert, of Kauert & Doehler, machinery dealers, Toronto and Montreal, has gone to Europe on business.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

UNIVERSAL AND TOOL GRINDING MACHINE.

A NEW Universal and tool grinding machine, illustrated in the half tone, herewith, was recently placed on the market by the Brown & Sharpe Mfg. Co., Providence, R. I. In construction it differs materially from other products of this type. It will take work up to 18 inches in length and will swing 12 inches in diameter. This machine is specially adapted to the grinding of milling cutters, formed cutters, straddle and face mills, beveled and angular cutters, end mills, straight or taper reamers, etc. Cylindrical grinding, straight or taper can be done, and with



No. 12 Universal and Tool Grinding Machine.

the attachments that can be furnished if desired, internal and surface grinding can also be accomplished.

The design and construction, as shown by the cut, gives evidence of a careful study of the requirements for a grinding machine of this type in securing the greatest efficiency, together with accuracy in the finished product. There is exceptional rigidity and freedom from vibration, owing to the disposition of the metal; for example, the base and column are cast in one piece, thus affording a rigid support for the wheel spindle, and the knee which carries the saddle and table is well braced internally with stout transverse sections. The spindle head has a transverse adjustment of 1½ inches, a vertical adjustment of 4 inches, also a radial adjustment to any desired position. The main movements are obtained in the knee which slides on ample ways on the column, in the saddle mounted on the knee, and in the sliding table which rests upon the saddle. The cone has 2 steps, is driven by a 1 inch belt, and the speeds are 3,180 and 3,970 revolutions per minute.

The sliding table is operated by a crank located on front of the saddle and has a longitudinal adjustment of 26 inches, a transverse adjustment of 8 inches, and a vertical adjustment of 10½ inches. The table can be swiveled 45° either side of central and securely clamped in position; the setting being facilitated by a graduated surface on the swivel table. Adjustable stops are also provided. Both the transverse and vertical adjustments are obtained by means of the handwheels conveniently located on the front and side of the machine respectively. They are graduated to read to thousandths of an inch. The saddle and table ways are wide and long, insuring rigidity and correct alignment. Metal guards afford ample protection against dirt and grit.

A variable speed mechanism consisting of multiple friction disks located at the side of the machine furnishes 16 changes of work speeds varying from 110 to 530 revolutions per minute. To change the speed it is necessary only to move the lever to a position opposite the required speed; the variations being shown by figures cast in the cover of the mechanism. The lever at the front provides means for starting and stopping the mechanism independent of its drive. The speeds are transmitted to the headstock by means of a flexible shaft. By such a drive a high efficiency is obtained and a wide range of speeds is possible.

In a machine of this type, the provision for wet grinding is an unusual and valuable feature. A tank is cast around the base of the machine which not only enlarges the capacity, but also increases the weight, an additional advantage. The waste water is well taken care of; suitable guards prevent the spray from wetting the floor.

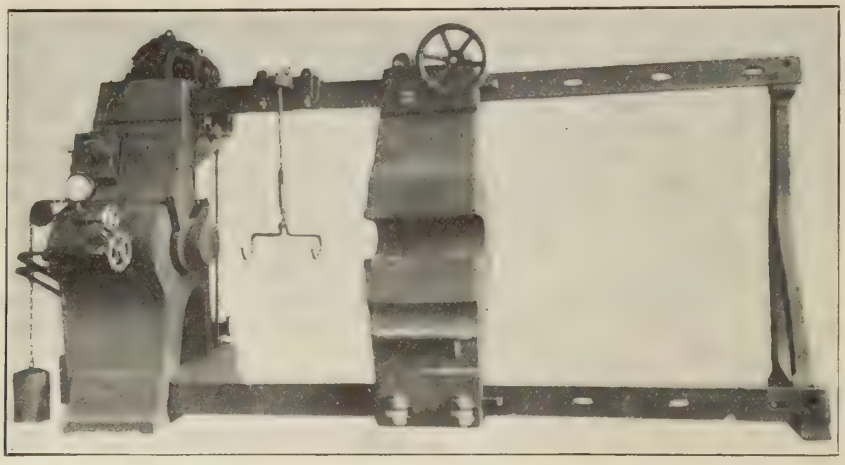
The value of a cutter grinding machine is greatly increased by the convenience with which it can be operated and cared for. To this end, the location of the levers and handwheels should be noted. All movements are controlled from the front, likewise the changes of work speed. The protection of working parts has been given careful attention, the ways being always covered and all oil holes and parts needing frequent adjustment carefully protected.

MOTOR-DRIVEN HYDRAULIC WHEEL PRESS.

BESIDES being used in all car and locomotive shops, a wheel press is now considered indispensable to the equipment of steam and electric railways, lumber yards, coal yards and mines, machine shops, foundries, cement plants, ship yards, dock companies and other concerns using a large amount of machinery or rolling stock.

The motor-operated wheel press shown in the accompanying illustration is a highly perfected machine, and attention is directed to its convenience in operation and simplicity of construction. For convenience in handling heavy work such as locomotive drivers and irregular shaped work that cannot be rolled to and from the press, the upper horizontal parallel bar is not directly above the lower, but at a slight angle, which permits handling the work with an overhead crane. The plungers (not shown in the photograph) are operated by

eccentrics on the back shaft, which is driven by cut gears having 3½ to 1 ratio. The plungers operate without vibration, and are practically noiseless. The ram is drawn back automatically as soon as the pressure is shut off from the pumps. An extra valve to connect with the city water line is furnished when it is possible to have such service.



Motor-driven Hydraulic Wheel Press.

By opening this valve (before using the pressure from the pump) the steel-faced ram is moved out against the work more rapidly than it could be done by the pumps, the city water line valve being afterwards closed, the pump valve opened, and the plungers started.

Pump Equipment.

The press is equipped with low and high pressure pumps. The former operates the ram up to a certain pressure with greater speed than does the latter, and consequently increases the amount of work that can be handled by the use of a high pressure pump alone. The low pressure cylinder is arranged with a relief valve, so that the pump works until about 50 tons is reached, when it automatically cuts out; the pressing operation being continued at a slower rate with the high pressure pumps.

The pump cylinders are cast from a special semi-steel mixture, giving great strength, and making them proof against leakage. All presses are provided with a safety valve to prevent overloading, and the plungers are driven by a direct current, 7½ horse power, Westinghouse motor. E. R. Caldwell & Co., Bradford, Pa., are the builders of this press.

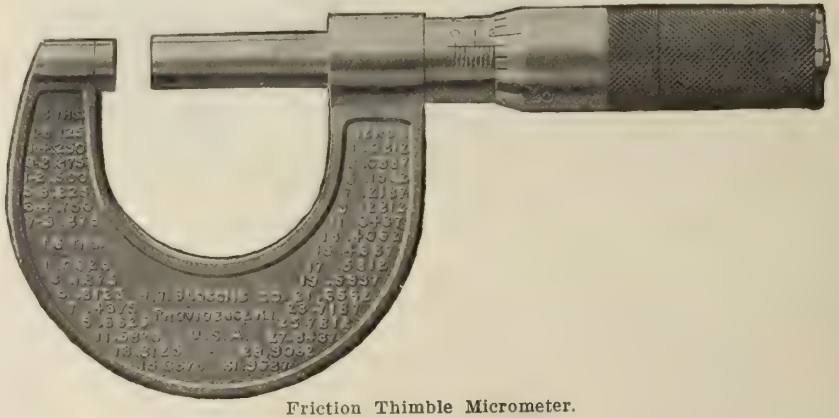
FRICTION THIMBLES ON MICROMETERS.

FOR several years past, the different manufacturers of micrometers have been fitting, when instructed, a friction or ratchet stop on the end of the thimble. The purpose of this was to overcome the difference in the "feel" of the different parties measuring. One man might have what is called a "heavy feel" and another a "light feel," and if a micrometer without this friction or ratchet stop were used, they would obtain a different measurement. In using the stop the ratchet or friction slips when more than a certain amount of pressure is applied and so prevents the measuring screw from turning further. This has an added advantage in that there is no danger of springing the frame. We claim an advantage in the friction over the old style ratchet in that it is much more smooth in its forward action and fully as positive in the reverse action.

The cut shows the friction stop which (when instructed) is put on any of the Slocomb micrometers. This device consists chiefly of a coiled flat spring of German silver. The inner end of this spring is attached to a washer, which is clamped to the end of the thimble by shoulder on central screw. The outer end slides around inside of large bore in the outer revolving part, and is so arranged that in turning to the right the device slides over the spring; but in turning to the left, the friction uncoils the spring, causing it to drive positively in this direction. The device has no parts that are liable to get out of order, and allows for a large and substantial screw for attaching; it also allows of reducing the knurled part to a small diameter, so as to provide a speeder as well. The German silver spring does not require lubrication and is not liable to lose its tension. Another advantage is the absence of click, which not only makes a ratchet-stop rough in its action, but prevents it stopping as positively as does this friction device.

The friction thimble is based on the same principle exactly, but the micrometer thimble is so constructed that the knurled part of the thimble revolves, instead of simply the end. The advantage of this is, that the friction may be worked with the same hand which holds the tool, while with the stop, it is necessary to hold the work in a vise; the tool being in one hand and the friction being operated with the other. With the friction thimble, the work is held in one hand and the tool in the other; the friction being worked by the thumb and forefinger of the hand holding the tool. This is of immense value in making quick measurements, and the friction thimble may be used in this manner even although the micrometer is opened to its full capacity.

The friction thimble does not prohibit the micrometer being used in the regular way, that is, the same as one without either friction thimble or friction stop, because the friction thimble only extends over a little more than half the full length, therefore, while it can be used, when opened to its limit, still one may operate the screw without using this feature when desired.



Friction Thimble Micrometer.

This device is furnished only on the polished pressed frame micrometer No. 26, which has the decimal equivalents raised on the frame. This tool has the same adjustment feature as the other Slocomb micrometers; the two nuts giving a long bearing for screw and making a fine adjustment. The J. T. Slocomb Co., Providence, R.I., are manufacturers of the apparatus.

FOUNDRY PRACTICE AND EQUIPMENT

CASTING PIPES WITHOUT CORES.

THE cost of producing cast iron pipe has up to the present been very largely augmented by the fact that it is necessary, in order to produce a uniform and even bore, to employ a length of dried sand core equal to the total length of pipe section to be cast. It is, of course, not possible to cast good pipes in green sand when pouring the metal into a stationary mold with a core, partly because the iron in falling down into its position would wash away the surface of the mold, and also because the green sand mold cannot withstand the great pressure exerted by the molten metal. The present standard practice, therefore, makes it necessary to go to the expense of cores, utilizing core ovens for drying purposes, and also drying ovens for the molds.

Quite apart from the initial cost incurred in such methods, there is a serious loss of time in preparing the molds and cores; necessitating considerable manual labor and a larger storage space, than would be required if a satisfactory means for eliminating this cumbersome method could be adopted. In times past, patents have been issued for the purpose of producing a cast iron pipe without the use of cores, but so far as can be judged from the results of actual practice, it does not appear that anyone until recently has been able to cast pipes in a continuous manner in standard lengths.

Recently, however, a process has been developed by Mr. Hermann Molinder, of Soderhamn, Sweden, which appears to be successful in producing good sound pipes without the use of cores. This marks a radical departure in the method of making this particular product, and as cast iron pipework is one of the most extensively used manufactured iron products in existence, in connection with civil engineering, gas, and hydraulic undertakings, it may be useful to refer to this new process with some amount of detail.

Molinder Process—The Mould.

Fig. 1 shows, both in longitudinal and cross sections a rotary mold, designed for founding such tubes. A frame supports the mold in ball or roller bearings. The outer casing of the rotating portion is conical, and made of cast iron without longitudinal separation. Within is contained the casting box, which is also made conical, of cast iron, and without longitudinal split. This casting box, lined with ordinary molding sand, either in the dried or green state, is introduced into the outer casing through one of the ends, and is coned so that it is always correctly central with relation to the ball bearings upon which the outer casing rolls.

It will be seen that the wall of this casting box is provided with a series of openings. In this way the gas generated in the lining as the molten metal is poured upon it, can escape through the openings into channels formed between the casting box and the outer casing. These channels are constructed in such a way that they do not interfere with the flanges which are provided in order to centralize the casting-box with the casing.

The drawing shows the position of the tube which is being cast, in relation to the flask; this tube being shown in solid black section. At each end of the flask is a cover which can be removed when the box is being lined with sand or when the tube which has been founded is removed from the mold. As the box is slightly conical and has a very even surface, the tube can be removed without the mold being divided into two parts along its diameter. At each end of the whole revolving arrangement is provided a pouring channel through which the metal is introduced into the box. At the top of the longitudinal section will be noticed two pieces acted upon by spiral springs fixed in the casing; these pieces being hinged to the casing as shown in the cross-section. It will be noted that one of the flanges giving support to the inner casing of the flask bears against this hinged piece; the object of the arrangement being that if it is inconvenient to remove the cast tube before the heat of the molten metal within causes it to expand, the spiral springs yield to a sufficient extent and prevents the box from becoming jammed in the casing or breaking it. It is then possible by unscrewing the nuts to relieve the pressure sufficiently to enable the casting box to be removed.

The casting box and outer casing are revolved by means of a toothed or

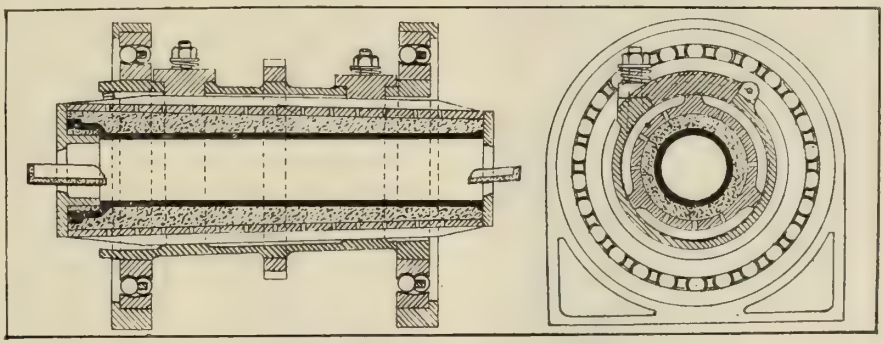

Fig. 1—Rotary Pipe-Casting Mould.

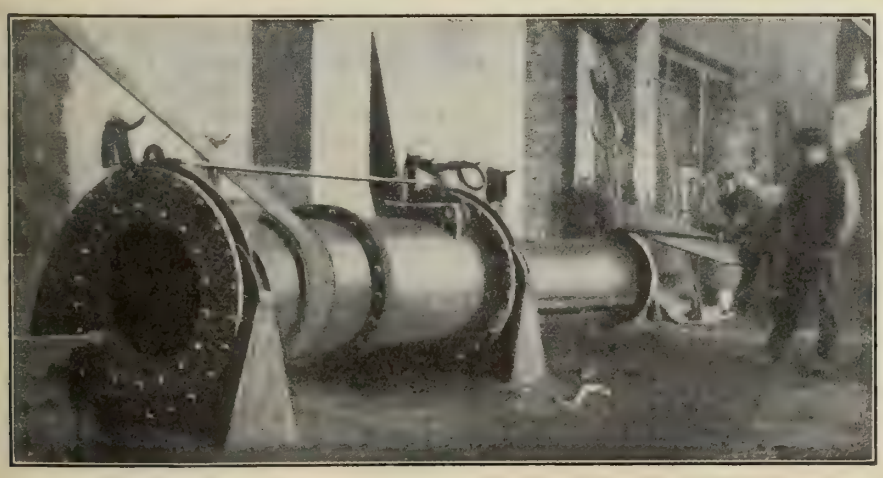

Fig. 2—Pipe Casting Machine, showing introduction of the Casting Box.

sprocket wheel fitted on the casing, or by means of a pulley, while suitable gearing is provided for the purpose of applying motive power. The casting box is charged and lined with fresh moulding sand for each casting operation, therefore, different types of tubes, as, for example, socket tubes, tubes provided with longitudinal and transverse ribs, and tubes with fixed end flanges can be easily manufactured by changing the pattern. Moreover, by using interchangeable casting boxes there is no time for the box to become so hot before the changing operation that it heats the outer casing. For this reason it is possible to use ball or roller bearings for the purpose of rotating the mold. The advantage in making the construction slightly conical will be seen when it is remembered that whilst the casting box is being dried its material is heated to a greater or less degree, and it therefore increases slightly in size.

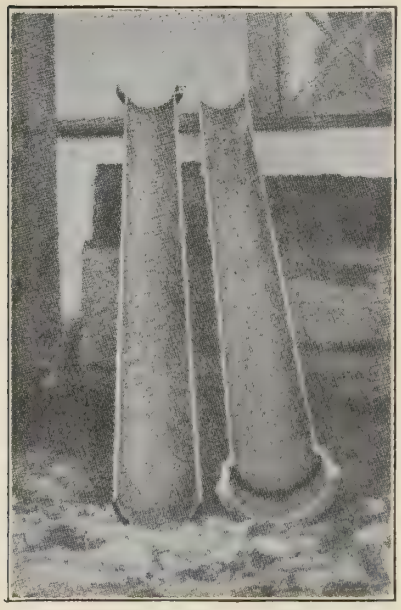

Fig. 3—Sections of Pipes.

It is found in practice that the temperature of the casting boxes can never be so carefully regulated that they always have the same size when pushed into the outer casing; because one box may have a temperature of 150 deg. Cent., while another may be cold. As all the boxes and the outer casing have the same cone angle, however, the former can be centralized under all circumstances, the only difference being that a cool box can be inserted into the outer casing further than one of higher temperature.

Molinder Process—Operation.

In operation, the mold is revolved at a speed great enough to make the centrifugal force sufficient to throw the iron outward as fast as it is poured, and in such manner that it flows out, and produces a more even thickness than it is possible to obtain by other methods. Ramming up the flasks is performed in the usual manner, except that great care has to be taken to have the pattern well centred. When casting pipe by this centrifugal method, it is sufficient to run the mold at such a speed that the centrifugal pressure exerted by the molten iron against the walls of the mold is about equal to that of an iron column 8 in. high. This pressure can be easily withstood by green sand, and it has been found by experiment with such molds that with good refractory sand the pipes come out just as smooth as with dried molds.

Putting in, casting, and taking out the flask by the method described above takes about eight to ten minutes, and about twenty to thirty minutes after pouring, the flask will have expanded sufficiently from the heat to drop the sand and casting when it is hung vertically with the wide end downward. When this has taken place the flask goes back to the ramming pit. It should be mentioned that the flask is taken out of the machine about four or five minutes after pouring. If slag or sand enters the mold when the iron is being poured, it separates to the inside of the pipe, because it is of less specific gravity than the iron itself. This is a most important feature, because owing to its position it can be scratched loose by a suitable tool about two minutes after pouring, while the mold is still in motion, thus ensuring a clean casting. Pipe founders will appreciate this, inasmuch as it is always found that some slag will separate from the iron, although apparently quite clean when poured.

Fig. 2 gives a photographic representation of one of these pipe-founding machines, with the casting box just being introduced. From this, the general arrangement will be observed. The iron before pouring must, of course, be weighed and measured. This is usually performed as follows:—When pouring a number of pipes of the same size, the first ladle, when it contains a sufficient amount of iron, is weighed and a mark put on the ladle, by means of which it can always be judged when there is sufficient iron in it. In taking the iron directly from the blast furnace for casting purposes, the greatest trouble, generally found, is that the iron contains more graphite than it can hold, causing unsound castings. It appears reasonable, however, to suppose that the centrifugal method will do away with this trouble when casting pipes, since all light particles separate to the interior. After the iron is poured, the graphite can be seen in the pipe; it having an appearance like red-hot dust, while the whole pipe is still fluid. Since all slag and dirt in such pipes separate to the inside surface, the iron must of necessity becomes more homogeneous than in pipes cast in the usual way. Figs 3 and 4 show specimens of fractured pipes, evidencing great regularity of cross-section.

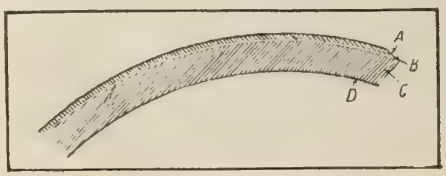

Fig. 5—Section of Pipe.

Tests and Analyses.

A number of tests and analyses have been made on these products. Four pipes, each of 9 ft. 10 inches long, 7 7-8 inches in diameter, and 13-32 inch thickness,

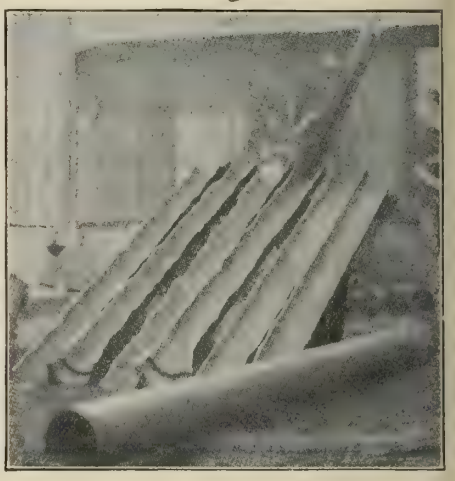

Fig. 4—Fractured Pipes, showing even section

were tested at an hydraulic pressure of 50 atmospheres, or, say, 750 lb. to the square inch, without leaking or sweating being detected. Pipes cast in the ordinary way, when tested to a pressure of 20 to 30 atmospheres will show, usually, a good deal of leaking and sweating, due to their lack of homogeneity, brought about by the presence of slag and graphite. Table I. gives results of seven different analyses made on the same pipe. This should be studied with reference to the sketch, Fig. 5, illustrating a section of the pipe. It will be seen in the sketch that three different layers are indicated, but they are not quite so sharply marked in the actual castings as here shewn. Analysis No. 1 is taken in the layer marked A; Nos. 2 and 3 are taken in B; while Nos. 4, 5, 6, 7 refer to samples taken in succession towards the inside surface, and in such a way, that No. 7 is the inside surface when the skin was turned off.

The cast iron used did not contain more graphite than it could hold when cast in the ordinary way, but when using the centrifugal methods, it will be seen by the analyses that some of the

graphite is proceeding towards the inside of the pipe while the iron is still fluid. The seventh analysis, however, shows less graphitic carbon than Nos. 5 and 6; probably because of the fact that the inside skin or surface solidifies a moment or so earlier than the iron underneath it, which still continues to gather some graphitic carbon against the skin thus formed.—The Engineer.

A. B. JARDINE & CO., HESPELER, ONT.

A. B. JARDINE & CO., Hespeler, Ont., entirely re-modelled their plant recently and added a new machine shop and foundry. These have now been in full operation for several months and give employment to about 50 men. The firm are perhaps best known as makers of high-class taps and dies of all kinds, standard and special. They also make bolt threading machines, tube expanders, blacksmith and carriagemakers' tools and machines. A full set of jigs and similar appliances has been got up for the various lines manufactured, so that all like parts are absolutely interchangeable, as was conclusively demonstrated to us on the occasion of a recent visit. To the foundry must be given a large measure of the credit because the accuracy and smooth finish given to all castings is remarkable. Mr. John Jardine, the superintendent, is decidedly of the opinion that a little extra money spent in the foundry is more than repaid in the machine shop, especially in a plant turning out much repetition work.

The Machine Shop.

The new machine shop covers a space of 90x60 feet, and consists of three bays. It is exceptionally well lighted by numerous windows and by a clerestory roof over the centre bay. Artificial lighting is secured by 100-watt tungsten lamps suspended from the roof trusses, in addition to which ordinary carbon lamps are suspended over each machine. The machinery equipment is of an interesting and up-to-date description and shows ample evidence of being well cared for. A somewhat unusual machine to be seen here is a combined turret and engine-lathe built by Stevens & Hamilton—now the Stevens Company, of Galt. This lathe has a bed 10 feet long and is fitted with an ordinary apron, so that it can, when necessary, be used as a 20-inch engine lathe; the turret being then used to carry the tailstock centre. It is used chiefly for boring and chuck work.

The largest lathe in the shop is a 28-in. by 12 feet, McGregor-Gourlay engine lathe, which, by means of an extra countershaft operated by a clutch, makes it practically the equivalent of a double back geared lathe. All special taps are threaded on a Hendey 16-inch tool room lathe, fitted with quick change speed gears and relieving attachment. The chasing is done with a Rivett-Dock threading attachment. In the case of tapper taps, pulley taps, etc., an economy is effected by welding-on the shank in a Toledo electric welder having capacity up to 7/8-inch diameter. By changing the die points, the machine can be used for spot welding, and is so used for attaching the fan blades to the hub or spider of a very popular forge blower manufactured by the firm. Near this welder stands a Landis No. 3 universal grinder, fitted with internal grinding attachment.

Situated about the middle of the shop are several engine lathes designed many years ago, but still doing good work. As proof of this, we may cite the case of a 20-inch McKechnie-Bertram tool which forms one of the group. This lathe, about 30 years old, was lined-up and overhauled 3 years ago. Its condition is so good that it is always used when it becomes necessary to cut new lead screws for the automatic tap lathes hereafter mentioned. In doing this job, the ordinary lead screw is removed from the McKechnie lathe and a special precision lead screw substituted. The latter was supplied by Brown & Sharpe under a guarantee that the error would not exceed .003 inch in any 3 feet and would not be cumulative. Special gears drive this screw. These are designed to slightly lengthen the pitch of the head screw being cut. In this way the pitch of the taps is increased the correct amount to allow for shrinkage in hardening. Other machines in the centre bay include a Hendey 18-inch by 10 feet engine lathe and three 22-inch drill

THE PLANT OF A. B. JARDINE & CO., HESPELER, ONTARIO.

presses with sliding heads. One of these is by John Bertram & Sons, the other two being built by W. F. & J. Barnes. Bolted to a column nearby is an ingenious three-spindle drill. This was designed and built by A. B. Jardine & Co., and occupies very little space. The heads are arranged in a circle, and by means of an indexing arrangement any one of them may be brought into line with the driving spindle, which is then brought down and drives it by means of a small dog tooth clutch.

Further equipment to be noticed includes:—Three milling machines, one of which—a plain miller by Stevens & Hamilton—has been in continuous use for close on twenty years and during that time has only had the table and slides scraped and adjusted once. This speaks well for the construction of the machine and also for the care it has received in use. The other milling machines comprise a No. 2 Leblond universal and a No. 7 Becker-Brainard (Lincoln type) machine. The latter is used for milling flutes in taps. It has a special attachment for holding four taps at once, an independent cutter operating on each tap. There is an indexing arrangement by means of which, after the first flute is milled, the taps are simultaneously revolved through the correct angle for cutting the next flute. All taps, except specials, are chased on automatic tap lathes designed and built by the firm. There are five of these lathes, one operator attending to all of them. The taps are sized by Brown & Sharpe thread micrometers, which give the pitch diameter in the thread and are made within a limit of .0005 inch. These lathes, as well as other machines throughout the shop, have the work flooded from a common pipe system through which oil is forced from an underground tank by a small centrifugal pump.

All gear cutting is done on an automatic gear cutter made by the E. J. Flather Mfg. Co., Nashua, N.H. This will cut a gear 30 inches diameter by 9 inches face. Near this stands a 24x30 planer having an 8 feet bed, built by the London Machine Tool Co., and chiefly used for broaching, since the various lines manufactured call for very little planing. A Bertram 24-inch shaper and two power hack saws complete the list of the machine tool equipment; but in addition, there are several grinding and polishing stands for sharpening taps, polishing dies, etc., the dust from these being carried off by hoods and exhaust fans. The taps have the size, trade mark, etc., stamped on them by a marking machine built by the Dwight Slate Machine Co., Hartford, Conn. At one end of the shop is a small electro-plating plant in which die stocks are nickel-plated.

All machines are belt-driven from line shafting, running in ball-bearing hangers designed and made by the firm, the shafting being driven by several motors taking hydro-electric power.

The Hardening Process.

Taps, dies and other tools are hardened in a coal heated muffle, the temperature of which is checked by a Foster fixed focus pyrometer. On reaching the proper heat the tools are quenched in water kept at an even temperature by means of a circulating pump. They are afterwards tempered in an oil bath, the oil being heated in a copper vessel over a coal fire. When the thermometer in the bath shows the correct temperature, the taps, etc., are dipped into the oil in wire baskets and when heated, are cooled off in cold oil. Adjacent to the hardening room is a small blacksmith shop containing one fire and a 400 pound steam hammer by B. & S. Massey, Manchester, England.

The Foundry.

The new foundry employs five moulders at present, and as already mentioned, turns out some finely finished work. Large numbers of bevel and spur gears are moulded on a stripper plate moulding machine designed and built by the firm. A 28-inch Collian cupola is used and at present the largest casting made weighs 800 pounds. This is the casting for the firm's well-known 25-pound power hammer, which has proved so successful that patterns are now being got out for one of double the size.

Messrs Jardine & Co. supply a large number of taps, dies, etc., to the Grand Trunk and other railways and large manufacturing plants, while their hand drilling machines, tire upsetters and benders and other tools are in request amongst blacksmiths and wagon builders. Their Western trade is also extensive, not infrequently necessitating complete carload shipments.

OIL BATHS FOR GEAR BOXES.

AN interesting sidelight is thrown on the question of flooded lubrication for machine tool gear boxes in the following communication to Page's Weekly by F. W. S., Disbury, Manchester, England:—

A new machine driving through a geared driving box was undergoing efficiency tests. All the gears on the lower shaft of the driving box dipped into oil, contained in the lower part of the box. In testing, the splash of oil was so great that the force was sufficient to cause leakage at various joints. As a consequence, it was decided to carry on the test with a lowered oil surface. After completion of the test, which was to ascertain the power necessary to effect certain cuts, an examination of the power curve showed a big discrepancy, and this discrepancy appeared at the very point at which the change in oil surface had been made; hence it was decided to duplicate the tests last made, after replacement of the oil to bring it to the former level. The power figures were now found to increase from about 10 to 20 per cent., according to the speed, the conclusion drawn being that the additional oil resulted in this amount of loss.

Finally, tests were made to show the differences caused by varying the oil level, even to the extent of suppressing the splash altogether, with the result that the power needed was seen to increase uniformly as the oil level was raised. There is no doubt the extra power was entailed by the additional work to be done in moving the oil, all the gears acting, as it were, as pumps, and taking the power that a pump would require to do the same amount of work. After running some little time entirely without oil, power was found to increase, and examination showed that temperature at the bearings gradually increased. As a result of the tests, it was decided to reduce the oil level to the minimum requisite to ensure efficient lubrication, with an average saving in power of some 15 per cent.

Does not this suggest a return to some form of syphon or drip lubrication? A constant loss of, say, but ½ h.p. is a matter deserving of some little consideration and would well pay for the little additional cost of fitting special means for lubrication, and the trouble entailed in daily oiling.

DANGERS OF THE CASTING SHOP.

THE following notice which is framed and posted in the foundry of C. Cowles & Co., New Haven, Conn., should be of interest to foundrymen in general:—

When a person is burned by molten brass, if a slight burn, wash it first with a warm solution of a mixture of 50 parts of water, containing 2 per cent. of carbolic acid, and 50 parts of a strong solution of sodium carbonate. After the pain has subsided, a bandage should be put on saturated with a mixture of 80 per cent. strong lime water and 20 per cent. boiled linseed oil. When the blister that forms has broken or been reduced, the burn should be dressed with hydrogen peroxide diluted with one-half water. The wound will then heal. If

the burn is serious, call a physician, and pending his arrival, apply the carbolic acid and soda solution to the burned parts as gently as possible, and leave the rest of the treatment to the doctor.

CENTRAL RAILWAY CLUB OUTING.

THE fifth annual outing of the Central Railway and Engineering Club of Canada, took place on Saturday, June 22nd last, when about 150 members left Toronto by special train for the little town of Erin, Ont. Favored by magnificent weather, the excursion proved most enjoyable to all present. The train certainly broke no records on the outward journey, so that everyone was in fine shape for dinner by the time Erin was reached. In the afternoon a good programme of sports was carried out in the Stanley Park. a picturesque pleasure ground near the station. The chief item was a baseball match between teams representing the Mechanics and the Pedlars, for a silver challenge cup. The Pedlars won (8-6) thus reversing last year's result. Quoit matches, foot races, sculling matches on the lake and other events completed a well-contested programme, at the conclusion of which handsome prizes were distributed to the lucky winners. A band was in attendance and enlivened the proceedings with the latest airs.

C.P.R. ELECTRIFICATION.

The electrification of the Rossland division of the Canadian Pacific Railway in British Columbia is being pushed forward to determine the applicability of such a course under the heavy conditions to be encountered. The section to be electrified runs from Rossland to Castlegar Junction. The length of the Rossland division is 29.3 miles, which, with sidings and yard trackage mounts up to a total trackage of 43 miles. The motive power installation will consist of four 70 to 80-ton electric locomotives; power being obtained from the West Kootenay Power and Light Company at probably 60,000 volts. This will be utilized through motor generator sets in sub-stations located either at Trail or Smelter Junction. Systems using alternating current at 6,600 volts and direct current at 2,400 volts are being proposed.

Mr. Thomas Black, of Winnipeg, is negotiating with the authorities of Fort William to secure concessions for the erection of a wire and nail plant to cost between $150,000 and $200,000 and give employment to about 200 men. An option on a site has been secured, but the details of the agreement to be made with the city have not yet been arranged.

Trade Gossip.

The Eastern Car Co., organized as a subsidiary of Scotia to make steel cars, was organized at New Glasgow recently by directors of Nova Scotia Steel and Coal Co., and others. The capital is to be $250,000, and the plant will be constructed in New Glasgow with an initial capacity of twenty-five cars a day, giving employment to one thousand men. A former official of the American Car and Foundry Co. has been secured as manager. The new plant will be the third car works in Nova Scotia. All the capital was underwritten within two hours.

The Russell Motor Car Works, Toronto, are building another extension to their present plant on Weston Road South. A permit has been issued for the erection of a four-storey machine shop to cost about $10,000. The new building will be about 170 feet long and 60 feet wide, and will be situated just east of the new office building. The total cost of the equipment and building will be about $100,000.

The Smart-Turner Machine Co., Hamilton, Ont., have recently received the following orders:—R. M. Breckenridge, Burlington, Ont., triplex power pump; Geo. Frid & Son, Hamilton, Ont., duplex pump; Wettlauffer Bros., Mitchell, Ont., centrifugal pump; Joseph Battle, Thorold, Ont., duplex pump; the Western Construction Co., Courtright, Ont., duplex pump; Corporation of Dauphin, Dauphin, Ont., underwriter fire pump; the Wolverton Milling Co., Wolverton, Ont., rotary fire pump; The Hamilton Gaslight Co., Hamilton, Ont., duplex pump.

Swedish Steel and Importing Co.—Lammers &Carleson announce that they have assumed as a partner, Mr. O. Bergstrom, metallurgist and consulting mining engineer, and that the firm name has been changed to that of the Swedish Steel and Importing Co., Ltd., with head office in the Canadian Express Building, Montreal.

The Foss & Hill Machinery Co., 344 St. James Street, Montreal, have been appointed agents in their territory for the Detroit Twist Drill Company. A large and complete stock of all kinds and sizes of the well known "Detroit" brand of twist drills, reamers, cutters, etc., will be carried, facilitating prompt delivery, and especial service in the actual use of these well known tools that an exacting purchaser will appreciate. Attractive booklets illustrating and describing "Detroit" Drills, including some very practical information governing their use will be mailed by the Foss & Hill Machinery Company to inquirers.

Dominion Steel Corporation.—Mr. J. H. Plummer announced that the Dominion Steel Corporation will start the manufacture of nails. By putting the wire rods through this finishing process, the task of competing with duty-free wire rods from the United States is overcome, as nails come under the protection of the present tariff.

The Capital Wire Cloth & Mfg. Co. advises that its plant in Ottawa, Can., is being erected and it expects to occupy it an an early date. It is the plan of the company to be turning out its finished product, consisting of Foudrinier wires and paper mill wire cloth of every description, about July 20. The output will be for the Canadian trade. The building is to be of silicate brick construction, two storeys, 42 x 100 feet, and large enough to accommodate twelve looms. The building will have a blind end so that it can be conveniently added to as occasion demands. The company has the following officers: President, J. R. Buchanan; vice president, Frank Haefs; secretary and treasurer, J. W. Perazzo; superintendent, M. L. Peebles. They, with William Buchanan, constitute the directorate. All members of the company have been connected with the Appleton Wire Wks., Appleton, Wis., for periods ranging from five to sixteen years. William Buchanan is general manager of the latter concern.

The Page-Hersey Co., who have taken over the agreement made between the Corporation of Fort William, Ont., and F. V. Samwell regarding a tube works, intend commencing construction operations on a plant in the course of a few weeks.

The Imperial Steel & Wire Co., Collingwood, Ont., has converted $300,000 of its unsubscribed capital stock into cumulative preferred stock bearing 7 per cent. interest and ranking pari passu with the stock already issued. During the last three years the capacity of the plant has been increased from 15 tons to 40 tons of finished wire product daily.

The Canadian Morehead Mfg. Co. has been organized, with headquarters at Woodstock, Ontario. Return and non-return vacuum traps and condensers will be manufactured. G. H. King, Woodstock, is president and general manager.

The Canadian Boomer Boscher Press Co., Ltd., are making large additions to their plant in Montreal, which step has been rendered imperative by the large increase in business. The extensions comprise an addition 160 ft. long by 40 ft. wide to the machine shop; a new boiler house and a new blacksmith shop. The extensions will give the company large and improved facilities in all branches of their manufacturing and will naturally greatly increase the output.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

Montreal, Que.—Mr. W. W. Butler, Vice-President of the Canadian Car & Foundry Co., who has just returned from the coast, announced that his company would locate a branch in the vicinity of Vancouver. The Pacific coast plant will not be as large as the Fort William one, though the probable cost will be one million dollars.

Montreal, Que.—The plant of the Peck Rolling Mills was recently damaged by fire to the extent of $25,000.

Toronto, Ont.—The Canada Foundry Co., Lansdowne and Royce Avenues, Toronto, is erecting a foundry for the production of ornamental iron castings, at a cost of $110,000.

Ottawa, Ont.—What promises to be one of the largest plants of its kind on the continent is about to be built here in the form of new car works. The foundry will occupy about 120 acres.

Fort William, Ont.—The Fort William and Canada Car & Foundry Company expects to be operating in about fifteen months hence, and will then employ some thousands of men. The foundry will have a yearly capacity of about seven thousand cars.

New Glasgow, N.S.—The Eastern Car Foundry Company, Limited, have organized for the purpose of manufacturing steel underframes. The company is capitalized at $2,500,000, and will employ about 1,000 men.

Nokomis, Sask.—W. F. Terry has just opened his new garage and machine shop on Fifth Avenue. The shop has a large quantity of new machinery installed, and will be modern in every respect.

Toronto, Ont.—Fire broke out in the pattern shop of the Berg Machinery Company, on Bathurst Street, and did considerable damage before being checked.

Portage la Prairie, Man.—A fire recently destroyed the entire mechanical shops and storerooms of the Grand Trunk Pacific Railway, situated about a mile from here. Total loss was $50,000.

Welland, Ont.—The Canadian Steel Foundries Company is making a big addition to its plant here. The number of employes will be increased to 600, it is expected. The contract is held by the Hamilton Bridge Company.

Saskatoon, Sask.—The Saskatoon Motor & Machinery Works has been opened here. The organizers are said to be experienced machinists, and intend to develop an up-to-date shop.

Hamilton, Ont.—It is reported that the Steel Castings Syndicate will locate here and erect a foundry to cost $300,000, and to employ 400 men. The company is backed by Toronto, Hamilton, Brantford and Buffalo capital.

Prince Albert, Sask.—A fire, the cause of which is unknown, destroyed the plant of the Prince Albert Foundry Company here to the extent of $17,000. Insurance, $2,500.

Gananoque, Ont.—The Spring & Axle Company propose improving the shop to the extent of $10,000. When work is finished automobile springs will be manufactured.

Welland, Ont.—Plans are prepared for an extensive addition to the Page-Hersey Pipe Mills here. Pattern and pattern storage shops will be constructed, and contracts for same will soon be let.

MUNICIPAL.

Bracebridge, Ont.—Two by-laws were recently endorsed by the ratepayers. They provided for the raising of $5,000 re reservoir, and $7,000 for spring water extension respectively.

Barrie, Ont.—The Hydro-Electric by-law was recently sanctioned by the ratepayers. A by-law to raise $7,000 for extension of the Barrie electric light plant was also passed.

Waterloo, Ont.—The by-law to grant $10,000 as a loan to Chas. Kreutziger re erection of a box factory was carried by a majority.

Regina, Sask.—The ratepayers refused to sanction the bonus to the Ontario and Manitoba Flour Mills Company. By the proposed scheme the city was to guarantee the company's bond to the extent of $200,000.

Battleford, Sask.—The ratepayers sanctioned two by-laws recently. They provided for the raising of $100,000 for electric light extension, and $50,000 for building of sidewalks.

Wainwright, Sask.—The burgesses recently endorsed a by-law to raise $25,000 re erection of a flour mill.

Caledonia, Ont.—The Hydro-Electric Power by-law was passed by the ratepayers recently.

Coldwater, Ont.—The ratepayers voted in favor of the Hydro-Electric by-law recently submitted.

Minnedosa, Man.—The burgesses passed a by-law to raise $40,000 as a guarantee for the bonds of the Minnedosa Power Company.

Medicine Hat, Alta.—The by-law calling for the expenditure of $4,200 for industrial sites was recently approved by the ratepayers.

Port Arthur, Ont.—The burgesses recently passed the following by-laws:—$1,400 re street railway improvement; $11,500 for laying steel rails on the Fort William road; $15,000 for electric light extension; and $19,000 for a site for a public market.

Exeter, Ont.—The ratepayers recently endorsed by-law placed before them to raise $5.00 for the improvement of the sewerage system.

New Westminster, B.C.—The ratepayers have voted $400,000 for road and waterworks extensions and city enterprises.

Outremont, Que.—The by-law authorizing the council to borrow $400,000 was sanctioned.

Perth, Ont.—A by-law to loan the Perth Shoe Co. $25,000 was defeated by the ratepayers.

Eganville, Ont.—The Ontario Government will purchase $11,500 of debentures for school purposes.

Chilliwac, B.C.—The sewerage by-law which involved the loan of $75,000 was defeated whilst the following by-law was passed: Waterworks $144,000.

Niagara Falls, Ont.—The by-law appropriating $3,000 to purchase site for Pollard Machine Co. was passed.

Fergus, Ont.—The burgesses voted in favor of the Canadian Cereal Co. by-law, also in favor of the waterworks by-law.

Woodstock, Ont.—A majority voted in favor of the by-law to grant a loan of $3,500 to the Woodstock Automobile Manufacturing Company.

Regina, Alta.—The ratepayers carried by-law to raise $25,000 for publicity purposes.

Blyth, Ont.—The burgesses ratified by-law to grant a loan of $5,000 to the Blyth Flax Mill Co.

Macleod, Alta.—The by-law empowering the town to borrow $100,000 for municipal building was approved of by voters.

Port Dalhousie, Ont.—The by-law calling for the raising of $10,000 for electric lighting system was recently endorsed by the ratepayers.

New Hamburg, Ont.—The by-law granting a loan of $20,000 to the Electrical Specialties Company, was recently sanctioned by the ratepayers.

Amherstburg, Ont.—The ratepayers voted in favor of the loaning of $10,000 to the new automobile company and the new knitting factory just starting operations.

Nanaimo, B.C.—The ratepayers defeated the waterworks extension by-law which called for the expenditure of $15,000.

Lethbridge, Alta.—The burgesses recently endorsed the following by-laws:—$40,000 for electric light extensions; $10,000 for street railway; $25,000 for firehall, etc.; $39,000 re purchase of road roller; $83,000 re sewage system; $42,000 waterworks extension.

St. Johns, Que.—The ratepayers recently endorsed a by-law granting $10,000 to J. P. Mennier and J. Deneault as a bonus to a jewelry and plated ware manufacturing concern about to be started by them.

Port Arthur, Ont.—The ratepayers have passed a by-law whereby the city will buy 33 per cent. of the shares of the car manufacturing company about to commence business here.

ELECTRICAL.

Battleford, Sask.—The sum of $100,000 will be spent in the near future upon the extension of the electric light system here.

Galt, Ont.—The extension of the Hydro-Electric system here is being considered by the citizens. The cost of completing system will be about $45,000.

Grand Forks, B.C.—The British Columbia Copper Co. will shortly install an electric motor at Rawhide mine, at Phoenix.

Barrie, Ont.—The Barrie electric light plant is to be extended soon, as $7,000 was recently voted for that purpose.

Galt, Ont.—The ratepayers will vote on a by-law to raise $45,000 to complete the hydro-electric system of the city.

Lethbridge, Alta.—The sum of $40,000 will soon be expended for the extension of the electric lighting system here.

Minnedosa, Man.—The bonds of the Minnedosa Power Company have been guaranteed to the extent of $40,000 by the citizens here.

Coldwater, Ont.—The Hydro-Electric system is about to be installed here.

C.N.R. Repair Shops. — The office of chief engineer of the Canadian Northern Railway is engaged in the preparation of plans of the proposed railway repair shops and roundhouse to be erected this summer at Fort Mann. The repair shops will be 200 feet long and will be equipped with modern machinery. They will adjoin the round house which will have accommodation for fifteen locomotives. The material to be used in construction will probably be reinforced concrete.

C.N.R. Extensions. Sir William Mackenzie recently announced important road extensions for the future. Chief among these are the future plans of the Canadian Northern Railway for Ontario and Toronto. The president of the road stated that improvements to be made in the vicinity of Toronto will amount to many millions of dollars. They will include new yards and shops at Leaside Junction, and a new office building in Toronto, where the head quarters of the company will be situated. This will be one of the handsomest buildings in Toronto.

B.C. Merger.—The Schaake Machine Works, for many years one of New Westminster's foremost industrial enterprises, recently lost its identity when it merged with Heap's Engineering Works, of Vancouver. Mr. Heaps declined to make any statement as to the location of the plant, which it is understood will be considerably enlarged. No site has yet been determined upon.

Government Bounties.—The Dominion of Canada paid bounties for three months of last year, amounting to $300,000 on steel, lead, petroleum, etc.

Mr. Herbert K. Scott, M.I.M.E., of London, Eng., has sailed for Newfoundland on professional business.

Mr. E. Holt Gurney, of the Gurney Foundry Co., Toronto, Can., is on a three months' pleasure and business trip to Europe.

Caledonia, Ont.—The Hydro-Electric system by-law recently received the assent of the ratepayers, and preparations for its installation will soon begin.

PLANING MILLS AND SAW MILLS.

Nelson, B.C.—The receivers of the Yale-Columbia Saw Mill Company have decided to rebuild the mill which was burned down recently.

Bobcaygeon, Ont.—The Bobcaygeon saw mill was recently destroyed by fire, caused by lightning. The building was insured at $1,200, but this does not cover loss fully.

Galt, Ont.—Mr. Bailey has bought the old Scott planing mill on Ainslee Street, and new machinery will be installed, and the plant will be made up-to-date in everyway.

Coquitlam, B.C.—The Vancouver Timber & Trading Company has purchased a site for the modern saw mill they propose to erect near here. The capacity of mill will be about 200,000 feet per day.

Penetanguishene, Ont.—The saw mill of the C. Deck Company here was recently wiped out of existence by fire, believed to have been caused by an overheated bearing in engine house.

Nelson, B.C.—Fire recently destroyed the lumber mill of J. B. Winsaw, near here, the total loss of which is estimated at $50,000. No insurance.

Fredericton, N.B.—Moses Haines has erected a saw mill near mouth of Nashwaaksis, and will soon begin operation.

Lindsay, Ont.—Fire recently did damage to the extent of $3,000 to the planing factory owned by the Jones Hardware Company. Loss is partly covered by insurance.

Humboldt, Sask.—The Carberry Planing Mills Company have just completed negotiations whereby the company will erect a modern planing mill.

Lacombe, B.C.—The planing mill of the St. Paul & Tacoma Lumber Company was damaged by fire to the extent of $250,000. The loss is partly covered by insurance.

Byng Inlet.—Two saw mills of the Graves, Bigwood & Co. here were recently destroyed by fire. The mills are said to be among the finest in Canada, and their loss is keenly felt by citizens who are dependent upon them.

GENERAL MANUFACTURING.

Milverton, Ont.—Messrs. Hendrich and Lydt have been granted concessions by the ratepayers on the understanding that they will erect a large furniture factory. Building operations will begin at once.

Cobalt, Ont.—It is reported that M. J. O'Brien, of Renfrew, will build a 400-ton per day pulp mill. Land has been acquired and work is likely to commence at once.

Toronto, Ont.—The Canada Brick & Fireproofing Co., Ltd., have secured a charter from the Ontario Government, and will begin operations at once. It is capitalized at $500,000.

Berlin, Ont.—The Consolidated Rubber Co., Ltd., proposes to erect a factory here for the manufacture of automobile tires.

Windsor, Ont.—The National Auto Body Co., Ltd., which has been organized with $150,000 capital, is to construct a plant here, and are calling for tenders for same.

Coquitlam, B.C.—The Dominion Match Co. is about to erect here one of the largest and best equipped factories on the Pacific Coast.

Welland, Ont.—The grist mills known as the Brown's Mills, owned by R. Cooper, suffered loss through fire to the extent of $15,000.

Ottawa East, Ont.—The Ottawa Gas Co. has decided to build an auxiliary plant here, and six large gasometers will be installed at once, and all other requisites to make a thoroughly modern gas works.

Windsor, Ont.—A new automobile factory is about to be started here by the State Electrics, Limited. Temporary premises have been secured and a permanent plant is to be erected within a few months.

St. Thomas, Ont.—George Doolittle has purchased the buildings and plant of the St. Thomas Canning Company, and will use it for the extension of his trade in evaporated apples.

New Westminster, B.C.—The Royal City Mills here were recently destroyed by fire, and damage to the extent of $50,000 was done.

Park Hill, Ont.—The mill of the Park Hill Flour Company was a few days ago destroyed by fire. The loss is $15,000, partly covered by insurance.

Fort William, Ont.—The Great West Wire Fence Company are about to locate a factory here, and details will be announced later.

Harriston, Ont.—Francis Burns, of this place, is about to start up a factory for the manufacture of cheese cutters, cheese cases, refrigerators, show cases and meat cutters.

Leamington, Ont.—In nearly every part of western Ontario the Dominion Canners will

either improve the plants now in operation or erect new ones in preparation for the busy seasons. New packing establishments will be erected at Ridgetown, Forest, Jordan and Font Hill, Ont.

Belleville, Ont.—The first sod for the erection of the Ogilvie mill here was turned recently. The mill is 53 by 183 feet, and will be six stories high. The warehouse will be 178 by 170 feet, and its receiving capacity will be about 25,000 barrels of flour. The whole plant will cost $750,000, and will probably be completed in six months' time. W. H. Tann is the general superintendent.

Medicine Hat, Alta.—It is reported that a million dollar cement plant is about to be constructed here by the Canada Cement Company. No details are given yet.

Saskatoon, Sask.—The Saskatoon Tent & Mattress Company propose establishing a factory here, and building operations have been started.

Welland, Ont.—The Canadian Cataract Rubber Company have applied for a charter of incorporation, and will locate for business here. They will manufacture automobile tires.

Shoal Lake, Man.—The harness factory of R. Greenwood & Son is about to be enlarged, and workmen are now engaged on the erection of an addition.

Calgary, Alta.—The Western Canada Stone Company is organized with a capitalization of $500,000. The enterprise will employ about 300 men in the quarries. Alderman J. G. Watson is managing director.

Garden Hill, Ont.—The woollen factory here was recently struck by lightning, and fire did damage to the extent of $10,000.

Orillia, Ont.—It is possible that arrangements will soon be made whereby James T. Arnold & Company will locate a factory here for the manufacturing of upholstering material.

Sydney, C.B.—The Steel Company here will have a new cooperage mill, which will manufacture kegs and barrels for packing nails. The mill will employ 150 skilled men and helpers.

New Liskeard, Ont.—Extensive plans for a large canning factory are being made by Brillinger & Lang, of this place. It is expected the factory will be completed by September.

Colborne, Ont.—The Ohio Motor Car Company of Cincinnati are about to locate a Canadian branch here. A by-law granting a free site and exemption from taxation was passed by ratepayers recently.

West Toronto, Ont.—Amongst the many buildings that are being erected by the Swift Canadian Company at their plant at the corner of St. Clair Avenue and Keele Street is a soap factory. The building, eight storeys high, will be built of concrete. This company will be the first of its kind in Canada to manufacture soap. A short time ago a cottonseed oil refinery was built north of the company's abattoir and at present the company are erecting a $250,000 cold storage plant on St. Clair Avenue. This structure is also constructed of reinforced concrete.

BUILDING NOTES.

Toronto, Ont.—A new examining warehouse is to be erected here soon, to cost about $300,000. The exact site has not been selected yet.

Calgary, Alta.—A six-storey block, to cost $175,000, has been started here.

Montreal, Que.—Work has commenced here on the construction of two big structures on McGill Street, to cost about $1,000,000. Work is expected to be finished by April of next year.

Thorold, Ont.—The contract for the erection of the Ontario Pulp & Paper Mills has been let to Lackawanna Bridge Company of Buffalo. The mill will cost about $1,000,000.

Edmonton, Alta.—The Harvester Company are about to construct a warehouse which promises to be the largest of its kind in Western Canada. Details of the building are not given, but the cost will be about $250,000.

Port Arthur, Ont.—A ten-storey structure will shortly be commenced here. The new building, which will be one of the finest in Canada, will be used for business and commercial purposes.

Toronto, Ont.—The Doherty Manufacturing Company has secured a permit to erect an $80,000 six-storey warehouse of brick and stone on Spadina Avenue.

Wetaskiwin, Alta.—The plans for the automobile factory are completed, whereby the Vulcan Corporation are to erect a brick structure of large proportions.

West Toronto.—The Russell Motor Car Company will shortly start the erection of a new $100,000 building here. It will be four storeys high and 170 feet long by 60 feet wide.

The Canadian Boomer & Boschert Press Co. of Montreal have sent us their latest bulletin on veneer presses. The bulletin has ex-

cellent illustrations of single and double power screw veneer presses of various types. A few of the hydraulic presses are also shown. On account of the vast number of types of these latter it is impossible to illustrate them all. Copies of bulletin C1 will be sent on request.

CONTRACTS PLACED.

Hamilton, Ont.—The Des Moines Manufacturing Company, of Des Moines, Iowa, have received the contract to construct a water tower here, to cost $4,990.

Ste. Therese de Blainville, Que.—The work of installing a waterworks system to cost $75,000 for the Aqueduct Company of Blainville, Blainville, Que., is being done by the owners of the company under the supervision of Engineers Ouimet and Lesage, St. Lawrence Boulevard.

North Battleford, Sask.—The Canadian Westinghouse Company have received the contract calling for the supply and erection of a 500 kw. generator and equipment, the price being $5,580.

North Battleford, Sask.—Messrs. Laurie and Lamb have received the contract to erect and furnish a 750 h.p. steam engine, the price being $20,250.

North Battleford, Sask.—The contract calling for the erection and supply of a boiler has been awarded to Messrs. Babcock & Wilcox, Ltd., the price being $8,700.

Point Grey, B.C.—A $1,500 contract for the supplying of galvanized piping for use in extending the water supply system of the municipality has been awarded to Messrs. Robertson and Godson, of Vancouver.

POINTERS FOR CONTRACTORS.

Penticton, B.C.—The council of this municipality will call tenders on a 200 h.p. Diesel engine to be used as motive power in the lighting plant of the town.

Montreal, Que.—Plans and specifications are being prepared by T. Pringle & Son, Ltd., engineers, Montreal, for extensions to reclaim plant for the Canadian Rubber Co. Montreal.

Montreal, Que.—Plans and specifications are being prepared by T. Pringle & Son, Ltd., for a new slasher house for the Dominion Textile Co., Hochelaga branch, Montreal.

Montreal, Que.—T. Pringle & Son, Ltd., are preparing plans and specifications for a manufacturing plant for the N. K. Fairbank Co., Cote St. Paul, Montreal.

Three Rivers, Que.—Plans and specifications are being prepared by T. Pringle & Son for a new cotton mill plant at the St. Maurice Valley Cotton Mills here.

Toronto, Ont.—The Canadian Fairbanks-Morse Co., Toronto, are planning the erection of a large tractor shop on their property at Bloor Street west, Toronto. The plans and specifications of this building are being prepared by T. Pringle & Son.

Calgary, Alta.—Ratepayers of Calgary will shortly be called upon to authorize the expenditure of $1,053,600 for the improvement of a gravitation system which is supplying the city water. City Engineer Childs has submitted figures of the estimated cost The proposed plan is to duplicate the present pipe line from a point about two miles further up Elbow River than the intake of the present system, and run it into the city to join the city waterworks system at a point near the reservoir in southwest Calgary. Sedimentation tanks at the intake are provided in order to make the water as clear as possible, and a filter basin near the reservoir. The estimated cost of the new main is $738,600; the sedimentation tanks at the intake and the enlargement and lining of the reservoir, $15,000; and the installation of 12,000,000 gallon capacity filters, $200,000.

South Vancouver, B.C.—The Fire, Water and Light Committee has decided to ask quotations for 25 miles of 4-in. water piping and 10 miles of 6-in. water pipes, at an estimated cost of $70,000.

Toronto, Ont.—Assistant City Engineer George G. Powell has recommended the construction of 13 additional filters at the filtration plant, at an estimated cost of $735,000, along with a new pipe line to the tunnel, at a further cost of $140,000. The Board of Control has decided that plans and specifications should be prepared at once.

POWER PLANT NEWS.

Saltcoats, Sask.—The municipal authorities of this town are about to issue debentures for the installation of electric light facilities. The estimated cost for the work is placed at $17,000.

Beaverton, Ont.—The municipal council have applied to the Hydro-Electric Commissioners for a specific volume of current. Beaverton is the first municipality in that district to make such an application.

Guelph, Ont.—The annual report of the Light and Heat Commission shows that this

department has produced a profit of nearly $23,000 for the year ending December 31st, 1911. The following shows the manner in which this amount is made up:—

Total income	$110,188.35
Total expenditure	76,748.97
Net gain	$ 33,439.38
Debenture interest	10,738.85
Balance carried to credit of profit and loss account	$ 22,700.53

The income in the gas department was $55,495.34, and in the electric department $54,693.01. The total income was $110,188.35. Expenditures in the gas department were $37,603.59, of which salaries, $6,074, and labor (purification), $21,082.22, were the chief items. In the electric department's expenditure of $28,004.09, the cost of the Hydro-Electric power, $16,437.01, and $3,291.49 for general repairs were the chief items. There were $6,141.29 of general expenditures, and $5,000 depreciation, showing a grand total expenditure of $76,748.97. The balance sheet submitted by the auditors showed assets of $464,400.28, and total liabilities of $269,253.96, principally for debentures, due bank, city of Guelph and open accounts. The contingent fund for depreciation stands at $75,000, and there is a premium of $4,337.20, written up for reserve fund.

Montreal, Que.—The Montreal City Council are erecting a large central refrigeration plant at the Bonsecours market.

Charlottetown, P.E.I.—The Island Cold Storage Co. of P.E.I., are building a refrigeration plant at Charlottetown.

Montreal, Que.—The C.P.R. are installing a large refrigeration and ice-making plant at the Windsor Street Terminal, Montreal.

Montreal, Que.—Messrs. J. Robertson & Son, Montreal, are installing a cold storage plant upon the Carbonic Anhydride System. This is one of the very few plants of its kind in the Dominion.

Montreal, Que.—Messrs. Leonard Bros., fish merchants, Montreal, are extending their cold storage plant. The original plans and specifications for all the foregoing installations were prepared by Mr. Charles Bishop, Consulting Refrigeration Engineer, Montreal.

Vancouver, B.C.—P. Burns & Co., Ltd., are installing at their Edmonds Market a 1-ton Armstrong refrigerating machine.

Edmonton, Alta.—O'Donnell, Clark & Co., of Edmonton, Alta., have purchased from the Armstrong Machinery Co. a 5-ton Alaskan ammonia compressor, to be installed at once and operated on the brine system.

Montreal, Que.—A number of Montreal capitalists are interested in the formation of the Stadacona Hydraulic Company of Quebec, whose plant at Seven Falls, near St. Anne de Beaupre, will have an initial development of 10,000 horse-power. The entire output has been sold to the Quebec Railway, Light, Heat & Power Co., and to the Bayless Pulp & Paper Co. of Penn, who are establishing a large paper plant in the vicinity. There will shortly be a public issue of bonds.

CATALOGUES.

G. J. Worssan & Sons, of London, Eng., have sent us a catalogue of their "Zero" CO^2 freezing and cooling machines. The agency for these machines has been taken up by the Canada Caramel Co., 61 Dalhousie St., Montreal.

The Hill Electric Switch Mfg. Co., 65 McGill St., Montreal, have commenced the publication of a series of bulletins dealing with the lines they manufacture. These bulletins are perforated for purposes of filing. Bulletin No. 1 is descriptive of panel boards, and gives prices and sizes of all types of such equipment. They have also issued a circular on the "Ever Ready" pocket meter for testing either current or voltage. This instrument is particularly inexpensive, yet simple and accurate of construction.

Elbert Hubbard, the sage of East Aurora, has compiled a list of the world's twenty greatest men, about which he has built an essay, and refers to Joseph Dixon as "a man whose work has profoundly influenced civilization, yet, strangely enough, a man of whom the world at large knows little." This tribute to the founder of the Dixon Company is well worth reading, especially by those who wish to learn more of him, or by those who admire Mr. Hubbard's vigorous pen. Owing to a limited edition of this booklet, copies cannot be distributed except by request. The Joseph Dixon Crucible Company, Jersey City, N.J., will be pleased to honor such requests.

"Superheated Steam in Locomotive Service," by W. F. M. Goss, has just been issued as Bulletin No. 57 of the Engineering Experiment Station of the University of Illinois. It presents, in abridged form, the information which originally appeared as Bulletin 127 of the Carnegie Institution of Washington.

W. H. BANFIELD & SONS
TORONTO, ONT.

Price, forty cents. The use of high temperature steam in locomotive service represents an important development of modern practice. Bulletin No. 157 gives the results of a study of recent German practice in the use of superheated steam, the results of an elaborate series of tests made upon an American locomotive. The conclusions are to the effect that the use of superheated steam introduces no serious difficulties, that it brings about a material saving in the use of coal and water, and that it supplies the means whereby the power capacity of an American locomotive may be readily increased. Copies of Bulletin No. 57 may be obtained from the European sales agent, Chapman & Hall, Ltd., 11 Henrietta St., Covent Garden, London, W.C., England.

Bulletin No. 24, "The Economy Steam Turbine for Belt Drive," has just been published by the Kerr Turbine Co., Wellsville, N.Y. This bulletin shows belted economy turbine installations which are effecting marked economies over apparatus previously used.

The Ogilvy Engineering Co. have sent us a booklet on the Maxim Boiler. This gives diagrams and illustrations of the boiler, and deals with its most prominent features. Copies of this can be had by addressing Bank of Ottawa Bldg., Montreal.

The International Machine Tool Co., Indianapolis, Ind., have issued a booklet with the title of "Libby lathe work," in which are shown the size, shape and form of a few of the many pieces of work now being satisfactorily and economically machined on the **Libby** lathe. The times given are the average time in which the work is being done every day in actual shop practice, and will doubtless prove of interest to shop superintendents and foremen.

Marion & Marion, patent attorneys, of Montreal and Washington, have sent us a copy of the "Inventor's Adviser and Manufacturer's Hand Book on Patents, Trade Marks and Designs." The book gives a complete description of the method of securing patents and of points to be considered when obtaining same. It is a valuable acquisition to the library of any inventor.

BOOK REVIEWS.

The book **"Feed Water Filtration,"** published by James Beggs & Co., 36 Warren St., New York, has been in such demand that a fourth and revised edition has just been issued. This book deals with the removal of organic matter, oil, grease, and other floating particles from from boiler water, and illustrates and describes numerous installations of the Blackburn Smith Feed Water Filter and Grease Extractor. A free copy will be sent by James Beggs & Co. to anyone interested.

"A New Analysis of the Cylinder Performance of Reciprocating Engines," by J. Paul Clayton, has just been issued as Bulletin No. 58 of the Engineering Experiment Station of the University of Illinois. For many years the only accurate method of ascertaining the steam consumption of an engine has been to measure or weigh in some manner the water used. It has been discovered, however, that the quality of the steam present in the cylinder at cut-off controls the form of the expansion curve of the indicator diagram in a perfectly definite way. From this fact there has been developed a method of computing the steam consumption of an engine from the indicator diagram alone to within 4 per cent. of the actual consumption as measured by test. There has also been developed a method of obtaining the volumetric clearance of a cylinder using steam, gas, air, or ammonia to a degree of accuracy almost as great as the method of filling the clearance space with a known weight of liquid. The bulletin contains an exposition of the methods employed in obtaining the steam consumption and clearance, and also methods of detecting leakage from the indicator diagram with the engine in regular operation. Copies of Bulletin No. 58 may be obtained upon application to W. F. M. Goss, Director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

THE RAILWAY EQUIPMENT CO., OF TORONTO, LTD.

A RECENT addition to the industrial organizations of the Queen City is that of the Railway Equipment Co., of Toronto, Ltd. While the name indicates in a general way the nature of the firm's business, it may be here stated on the authority of information received by

our representative, that the work undertaken will partake more specifically of the repair, rebuilding, exchange and supply of electric railway equipment, consisting of trolley cars complete, car bodies, trucks, motor apparatus, individual motors, armatures, armature cores, field coils, etc. A well equipped repair shop, located at 1240-1250 Dundas Street, Toronto, forms a feature of the company's plant, and realizing the importance of the armature department, the management have secured the services of a superintendent of large experience to take charge of same.

The officers of the company are: President, William Harper, Toronto; secretary, Geo. H. Crow, Reading, Pa.; and treasurer, C. L. Allan, New York City.

TRADE NOTES.

The Murphy Iron Works, Detroit, Mich., recently executed their fourth order for Murphy furnaces from The Laurentide Co., Ltd., Grand Mere, P.Q. This firm have had experience of the furnaces since 1905, and their installation now embraces 14 sets, of a total of 4,250 horse power.

The Linde-Canadian Refrigeration Co. recently opened a branch office in Winnipeg which will handle all business in Manitoba and West as far as Calgary, Alta. Mr. F. H. W. Guard has left the Montreal office to take charge of this territory, and Mr. R. P. Mason has been appointed refrigeration engineer to succeed Mr. Guard.

Alberger Pump and Condenser Co.— Announcement is made, dated as from June 1st, 1912, that the three associated concerns, the Alberger Condenser Co., Alberger Pump Co. and the Newburgh Ice Machine and Engine Co., will in future be known as the Alberger Pump and Condenser Co. The officers of the new company are George Q. Palmer, president; William S. Doran and D. H. Chester, vice-presidents; and William R. Billings, secretary-treasurer. The head offices are at 140 Cedar Street, New York. The large amount of condenser and centrifugal pump orders in hand has demanded important additions to the plant and equipment of the works at Newburgh, N.Y. The line of apparatus manufactured by the Alberger Pump and Condenser Co. consist of surface, jet and barometric condensers of various designs, cooling towers, a complete line of volute and turbine type centrifugal pumps, steam turbines, feed water heaters, hot water service heaters, and expansion joints.

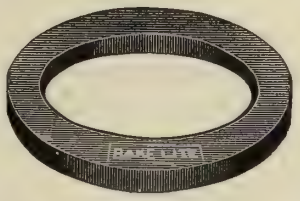
These are the telling points about

Bakelite

Valve Discs



They will not leak under high temperature, excessive pressure or when used in acids or other special liquids. Neither cold water, dry or superheated steam has the least effect upon them. **BAKELITE** Discs are a gas-tight fit.

BAKELITE is a successful substitute for expensive metal. Its structure is fibrous, giving strength and hardness. It can be reground and refaced, always retaining a uniform surface. It cannot be injured, except by accident or friction. Remember Bakelite **PUMP VALVES** do not warm with changes of temperature.

Order your valves fitted with Bakelite Valve Discs and stop that perpetual annoyance and expense caused by leaking valves. Depend upon it, Bakelite Valve Discs will not leak.

YOU WANT TO IMPROVE YOUR POSITION

THEN READ THE

LIFE OF JAMES WATT

INVENTOR OF THE STEAM ENGINE

By ANDREW CARNEGIE

An entertaining book for those interested in mechanics and power, dealing with the scientific and mechanical inventions of Watt's life and times and his relations with other noted scientists and inventors.

The author, as a practical engineer, possesses all the technical knowledge necessary to give actuality to his writing, and his book is alive with enthusiasm and appreciation. He has missed no point in the romance of Watt's career, with its many thrilling episodes and its study of human nature revealed in a realistic manner. Mr. Carnegie may not point out how to become a millionaire, but he certainly sets forth considerations which may help to influence many a working man to improve his position.

Cloth Bound. 164 Pages. Postpaid, $1.00.

AIR COMPRESSORS

Do you wish to make a saving in your Compressed Air System?

When you buy an air Compressor **do you look for** the machine with **the greatest amount of air valve motion?** Or do you buy the compressor **with the least unnecessary motion?** Can you **hear** your **compressor pounding** a block away from your works? Or can you hear yourself talk alongside of it?

In buying your machine **do you make a point of getting the compressor with the lowest up-keep cost,** both for repairs and oil?

The Belliss & Morcom Air Compressor does not require any motion rods to operate the air valves.

The Belliss Compressor runs quietly and smoothly.

The cost of up-keep for the Belliss Machine is practically half that of a great number of the machines now on the market.

Let us send you our pamphlet on Air Compressors.

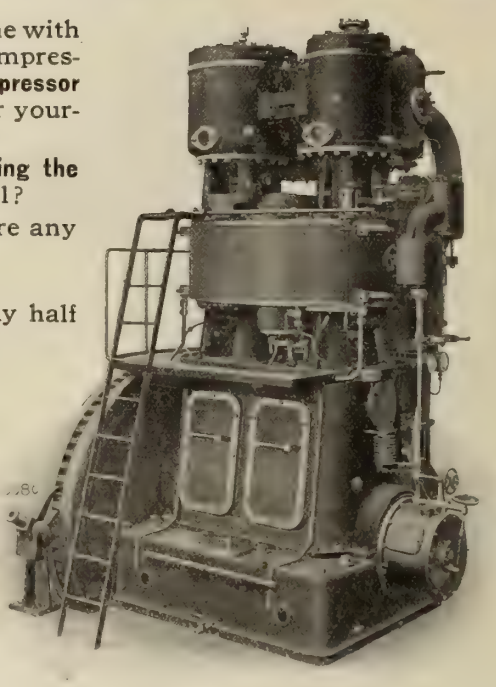
Manufactured by

BELLISS & MORCOM, Birmingham, Eng.

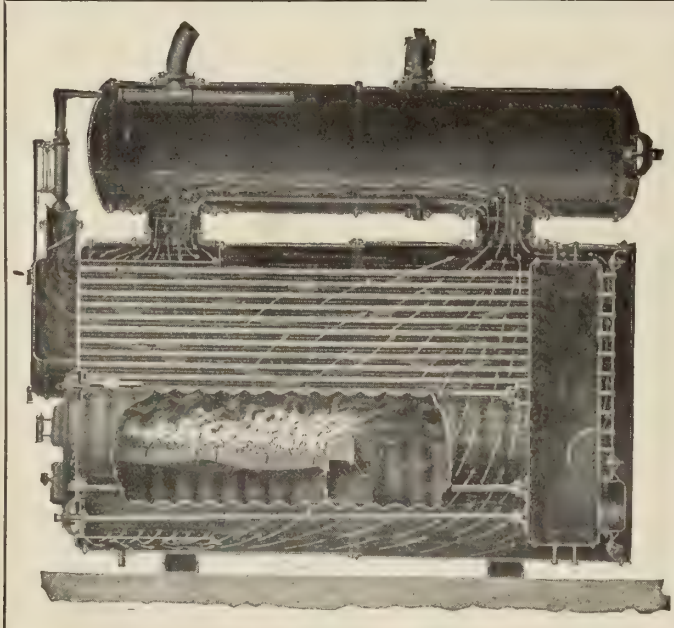
CANADIAN AGENTS:

Laurie & Lamb

Board of Trade Bldg. MONTREAL.



STEAM DRIVEN AIR COMPRESSORS



THIS new type solves the circulation problem The water beneath the furnace is constantly compelled to flow upward to the rear by the down-flowing feed water which comes through the front neck, as shown.

ROBB-BRADY SCOTCH BOILER

The Robb-Brady Boiler has a cylindrical combus tion chamber—engineers know what that means—no flat top, no crown bar or girder stays.

The large body of water in steam drum, neck and shell maintains practically the same temperature throughout the boiler, preventing unequal expansion.

Plants ashore can now have the efficiency of the standard Scotch marine boiler.

PHILA. U.S.A.

Taylor-Newbold Inserted Tooth Cold Saw

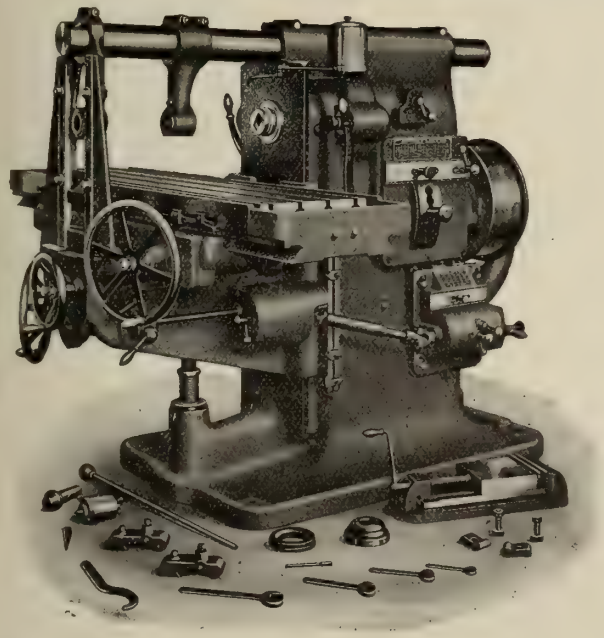
Standard Type for Steel Foundry, Forge and Machine Shop Use.

Special Type for Cutting Rails and Structural Shapes.

The TABOR MANUFACTURING CO.

18th and Hamilton Sts. - - Philadelphia, Pa

There is always plenty of work in railroad shops for which B. & S. Heavy Plain Milling Machines are adapted.



The No. 5 B Heavy Machine, our largest size, is shown in the cut.

Note the massive construction, large pulley to give a powerful spindle drive, and convenient arrangement of all levers and handwheels. These features are found in all **B. & S. Constant Speed Drive Machines,** and it is due to them that the machines are so successful in heavy milling.

Look around your shop and see the quantity of work that can be advantageously milled. Then write for special circulars of our machines.

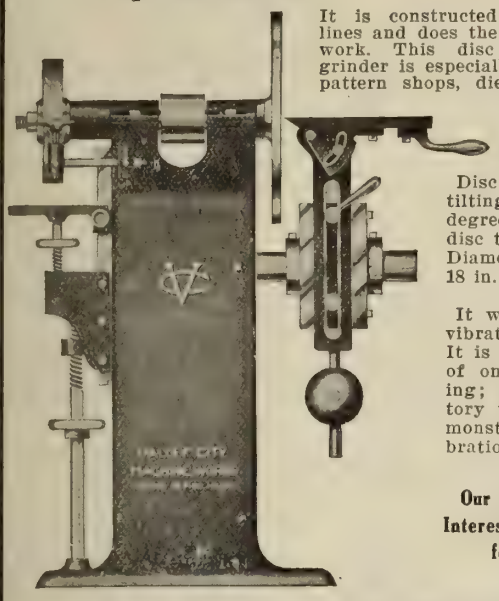
No. 9 Disc and Surface Grinder

Here is the Machine
That will Meet ***Your***
Requirements.



It is constructed on practical lines and does the finest kind of work. This disc and surface grinder is especially adapted for pattern shops, die makers, and all kinds of tool and surface grinding.

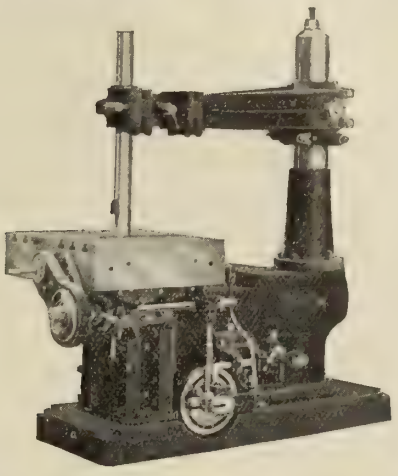
Disc side has table tilting from 0 to 43 degrees. Size of disc table, 10x10 in. Diameter of disc, 18 in.

It will solve your vibration problem. It is strongly built of one solid casting; and satisfactory tests have demonstrated that vibration is avoided.

Our Catalogue will Interest You. Write for it now.

VALLEY CITY MACHINE WORKS
20 Compau Street
GRAND RAPIDS :: MICHIGAN

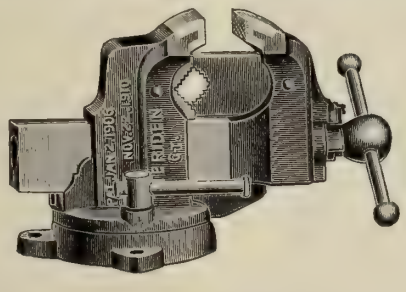
Keyseater and Slotter



Will cut keyseats, internal gears, internal ratchets, oil grooves, miscellaneous slotting, etc., more accurate and quicker than any machine on the market.

Baker Brothers, Toledo, Ohio.

Get Acquainted With
PARKER'S
Combination Pipe Vise
It Gives the Most Economical Service



This is a vise that has gained favor in many machine shops on account of its great convenience and service-giving qualities.

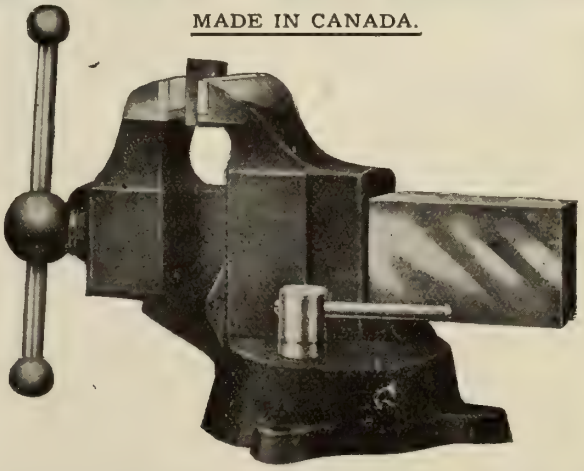
Fitted with **Solid Steel Bar**, and has **Removable Jaw Faces**, which are made of the **Best Tool Steel.**

All parts are interchangeable.

Write at once for circulars and prices.

The Charles Parker Co.
MERIDEN, CONN., U.S.A.

The YOST
Solid Jaw and Swivel Bottom Machinist's Vise
MADE IN CANADA.



A vise with a grip like grim death; a durability that defies time and the hardest usage.
A vise that will give you a lifetime of perfect service and satisfaction. The metal in a Yost Vise is of faultless quality, perfectly distributed and the workmanship is

Incomparably Good

The National catalog would certainly interest you. Write us, asking for a copy.

National Machinery & Supply Co., Ltd.
HAMILTON - - ONTARIO

This Guarantee Goes With Every Vise: We fully guarantee all of our Vises to be satisfactory in every particular and will promptly replace, without cost, any parts broken or badly worn when such failures are due to faulty material or construction.

BLOUNT'S

Grinding, Polishing and Buffing Machine

Does the Work of Three Ordinary Machines

At A SAVING of Labor and Space

It is perfect in design; well finished and smooth running.

Guaranteed to do the work equally as well as **three** separate machines.

Don't enlarge your plant because you need more space—install these machines.

Write for full particulars.

DESCRIPTION

Length over all, 5 feet 6 inches.
Height to centre of shaft, 38 inches.
Weight, 375 lbs.
Length from end of spindles to tight collar, 7 inches.
Length of Spindles, 30 inches.
Diameter of Spindles, 1⅜ inches.
Diameter of Spindles for wheel, 1¼ inches.
Tight pulleys, 5¼ inches.
Loose pulleys, 5 inches.
Crucible steel spindles.
Bearings extra long and babbitted with Phoenix babbit metal.
All bearings carefully scraped.
With or without Shifter.
Slight extra changes to meet special requirements without extra charge.
Fitted with Compression Oil Cups.
Pulleys turned inside and out and carefully balanced.
Strong and durable and made for extra hard usage.
A strictly high-grade machine and fully guaranteed in every respect.

PROMPT SHIPMENT GUARANTEED.

YOU ARE BUSY, SO ARE WE

We have no time to juggle arguments nor you to read them.

Therefore, why not get into action at once?

Try some of our steel. If it is not good, throw it out, it will cost you nothing. But you will not throw it out for it will give you satisfaction.

It is, as we claim, an improvement on other steels. We have the steel. Our claims are true. Our prices right.

Regarding the expense of your trial write to us.

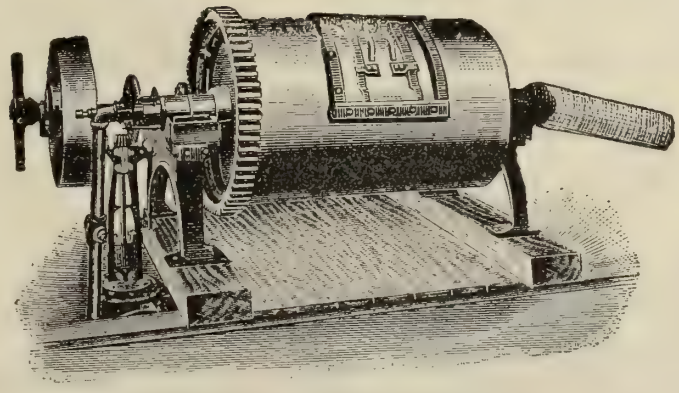
A GOLD MINE

SAVE YOUR IRON



SLY'S PATENT IRON CINDER MILL

Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

A WINNING HAND

THE Foundryman who uses **Stevens' Genuine East India Plumbago, or Ceylon Lead,** always plays a winning hand. He is betting on a sure thing.

I import this article direct from India, because it is absolutely the best plumbago produced in the workshop of Dame Nature.

It's use enables the foundry to do the work sometimes left for the machine shop to finish.

I manufacture everything used in a Foundry and in a Polishing and Electroplating Department.

In buying from me you are buying from first hands.

It costs as much to sell one thing as to sell them all. I sell them all for a small slice of profit. I take the small slice and give you the rest.

Take Time to Write Me a Letter.

THE TIGHTENING GRIP!

Foundrymen everywhere are being squeezed by a pressure that wrings from them their rightful gains.

They must pay a ***continual tribute*** to "Make-overs"—the profit devouring beast of their Foundry.

There is but one charm by which this beast can be destroyed—it is

SHELTON METALLIC FILLER

—the Foundryman's "Medusa".

DON'T PAY TRIBUTE

which means, ***don't make a casting twice!***

Make-overs are unnecessary.

Here is a chance to stop your losses.

Shelton Metallic Filler is guaranteed to fill in and completely obliterate blow holes, sand holes, etc.

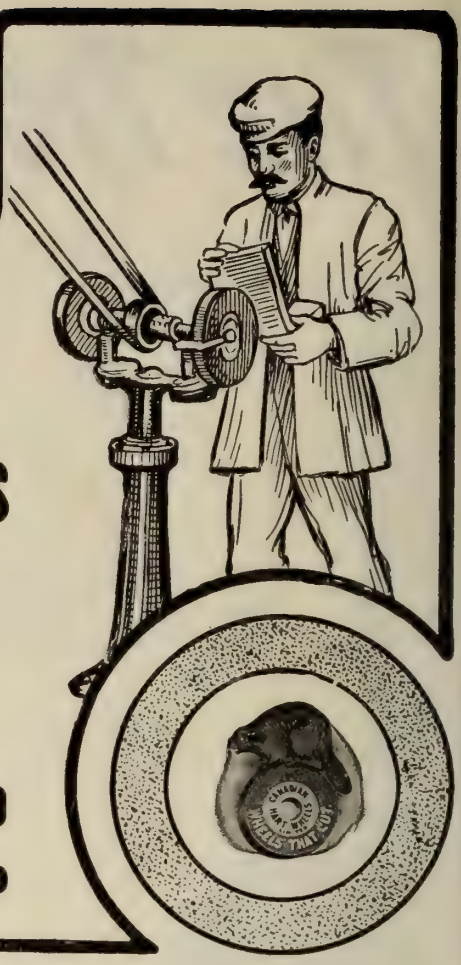
It becomes part of the casting itself, is durable, and can never be detected. It has been used with great success for many years.

Better write to us at once.

Shelton Metallic Filler Co.

DERBY, CONN.

The Daily Grind



The daily grind of mechanics engaged in using abrasive wheels is made much more effective if their machines are fitted with

CANADIAN HART CORUNDUM WHEELS

Our wheels are free and fast cutting, porous, safe, and very durable. Send for our catalogue which describes the various processes used in making Canadian Hart Corundum and Emery Wheels.

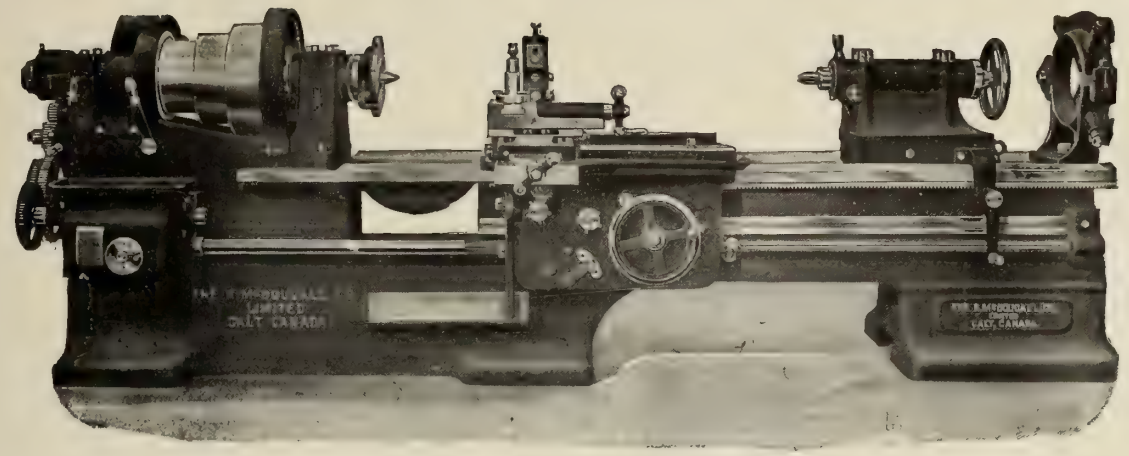
Great Reserve Strength and Capacity in this McDougall Lathe. Read About It. Details Below



NOTE the headstock construction first. See the very wide bearing surfaces and massiveness. The whole machine from head stock to base is like a solid rock. We have done everything that will make this headstock right. It must wear. It must resist strain.

The big bearings are fitted with deep oil chambers and ring oilers. Your lathe is automatically protected against accidental wear and excessive loosening up of the bearings by the operator's omission to oil. Only when you get wear taken care of, have you a headstock which is able to resist strain. Its wide bearings are not only kept automatically in shop perfection, but they take the greatest strain a cutting-tool can give through the work and a spindle in high-carbon steel. The automatic oil device protects the quality of your lathe output by protecting the bearings, so chattering is impossible.

Look at the work of a McDougall Lathe some day. You will see a smooth, clean tool-cut, shining and bright. This shows the even feeding of the work from a firm headstock against a firmly-held tool.

The carriage and apron are non-springing. The action of the tool depends on the solidity of bearing given it by the carriage. This carriage is supported by full "V" bearings, and flat bearings as well. There can be no "lost motion" in the carriage, and none at the cutting edge of the tool.

The tool feed reads to thousandths both ways on the compound rest The automatic feed is of the safety type, so interlocked that your mechanic cannot operate both feeds (screw and rod) at the same time.

Here you have a clean cut from a solidly-held tool working against a solidly-held casting, in a lathe so protected by automatic oiling that it always maintains its accuracy and strength. You can adjust this tool to 1-1000 inch. You cannot break tool or work by accidental operation of both feeds at one time. No breakdowns.

Now look at the tailstock. It has a quick-acting sleeve lock device. This permits quick change of work. In addition the tailstock is secured to the webbed and non-springing bed of the lathe by four bolts with top adjustment. Both kinds of tailstock changes are easy and quick—they save workmen's time.

Take another look at this McDougall Lathe. See how well the gap is supported, and how deep the gap is. Though this is a gap lathe, it is as solid as a standard type, because the base is carried under the entire gap opening. Here you have a gap lathe without a single disadvantage of the gap opening and the deteriorated work it often causes.

Get a McDougall Lathe like this in your factory equipment. Its adjustability, speeds, capacity and practicability make it one of the most perfect machine tools. It is particularly economical where a variety of kinds of lathe work have to be done on a single lathe, because it is a quick-change machine.

Suppose you write us your problem. And to-day, now. The McDougall lathe will raise quality and lower cost.

ASQUITH RADIALS

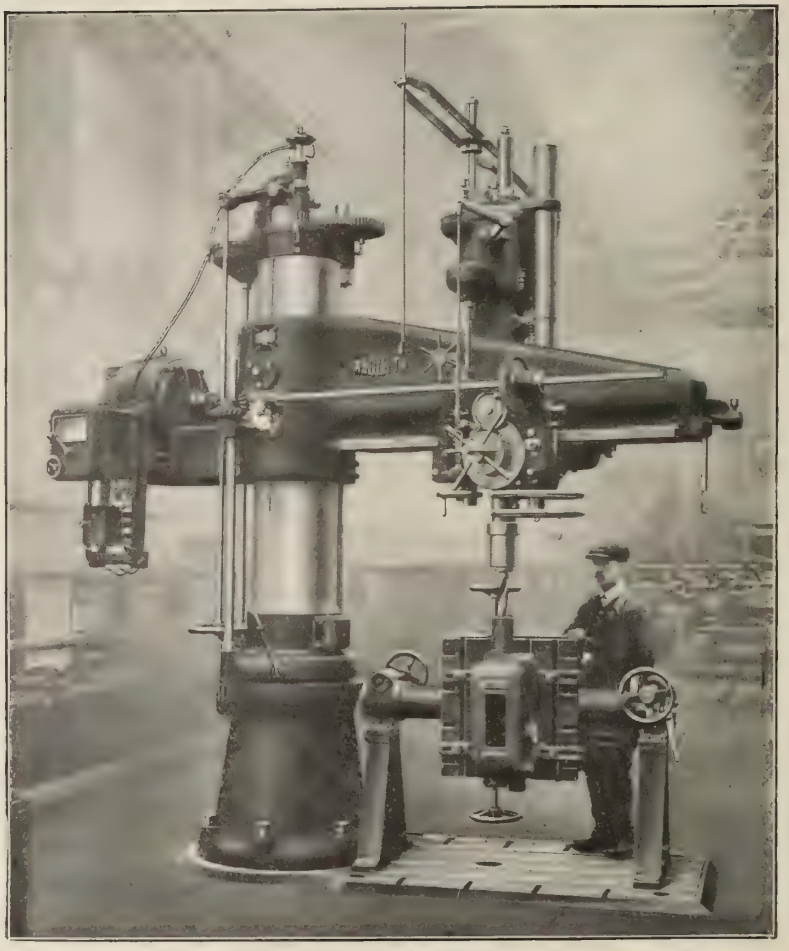
MAX. RADIUS OF SPINDLE, 6′-0″.

MIN. RADIUS OF SPINDLE, 2′-0½″

No. OF SPINDLE SPEEDS, 16.

No. OF SPINDLE FEEDS, 6.

VERTICAL ADJUSTMENT OF ARM 2′-10″.



NOTE:—

HEAVY COLUMN LARGE BEARING OF ARM ON COLUMN.

CENTRAL THRUST FEATURE.

GENERAL STRENGTH AND RIGIDITY.

6′-0″ Central Thrust, Motor-Driven, Radial Drilling Machine with Universal Tilting Table.

SLEEVE carrying arm is of large diameter, accurately fitted to standard, and has well extended bearings (greater than radius of machine), minimizing lift and ensuring greater rigidity. The sleeve can be easily and quickly revolved by hand upon **ball and roller bearings, yet has powerful locking arrangement.**

ARM upon which spindle slide travels is of **new improved patented form** and very strong construction, and so formed as to eliminate twisting strains, and give the greatest efficiency to the machine. The part bearing upon sleeve is of **great length.** The portion of the arm in which spindle slide works is of box girder type, the walls of which are of strong section and well ribbed to resist lifting stresses. The spindle works midway between the two long walls of the arm, ensuring **central thrust,** and entirely **eliminating side-twisting strains.** The lifting stresses consequent upon heavy drilling are by our **improved arrangement** distributed over a large flat horizontal area, and come entirely on the underside of arm walls, which are of great depth, even at extremity. **Lifting strains are thus brought to bear against a form of casting best calculated to overcome them, and reduced to such a minimum as to be practically negligible.** No other form of arm and slide can confer these advantages.

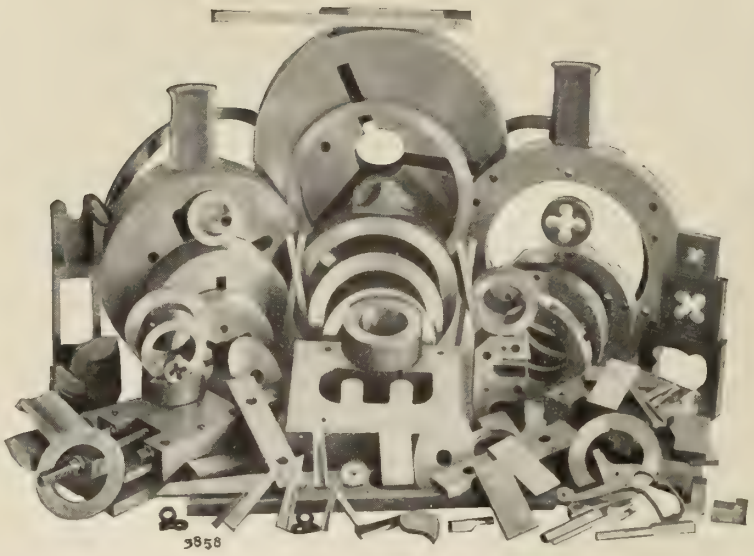
GRIND THOSE FLAT SURFACES



by the latest and most approved method—on the

P. & W. New Model Vertical Surface Grinder

We can prove it to be the most rapid, accurate and economical method.

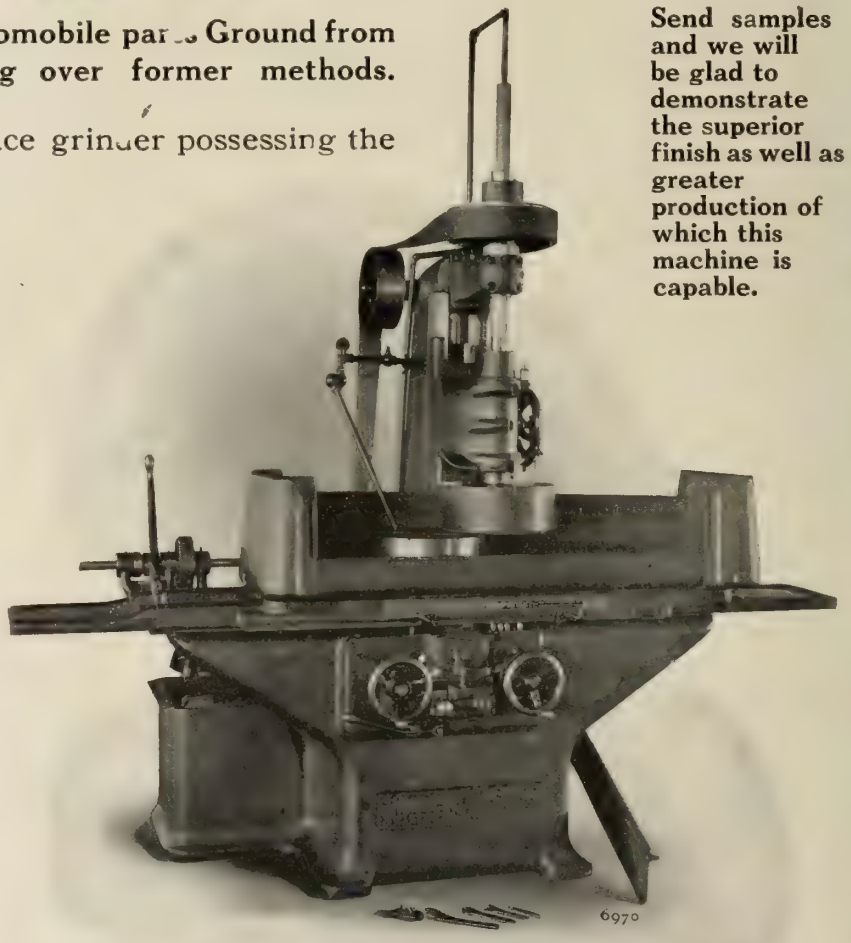
Cut illustrates a Variety of Automobile parts Ground from the Rough at a great saving over former methods.

This machine is the only surface grinder possessing the great advantage of the combination of rotary and rectangular, reciprocating chucks. Chucks of the magnetic type are furnished.

The entire control is at the front of the machine and the table is at a convenient height for loading.

Power and rigidity are in excess of the demands of the best wheel, which in conjunction with ease of operation, insures maximum output.

Write for illustrated circular "Vertical Surface Grinder." It will interest you.



Send samples and we will be glad to demonstrate the superior finish as well as greater production of which this machine is capable.

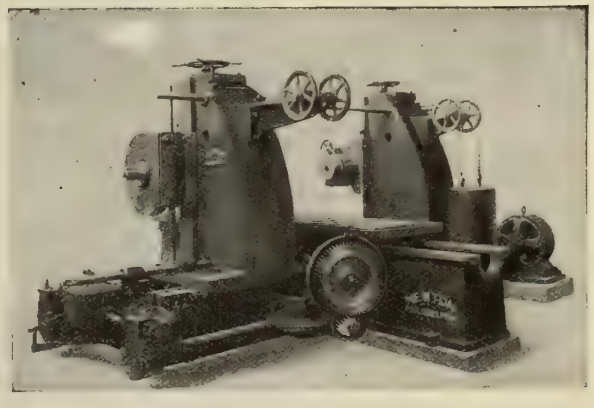
You can light your shop with the power your line shafts waste

IN any machine shop the line shafting wastes an average of 250 watts of power per machine, more than enough to light your shop brilliantly all day long. Stop this waste by using



Westinghouse Motor Driving Boring Milling Machine.

Westinghouse Machine Tool Motors and Controllers

The direct-connected motor eliminates all line shaft losses. With power at 5 cents a killowatt hour, this saving amounts to about $37.50 a year per machine.

But the saving in power expense is but one of the many advantages of the Westinghouse machine tool drive.

Westinghouse engineers are at your service to show you how to obtain the greatest production at the least expense.

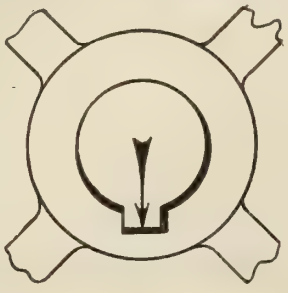
Our Broaching Machine is for cutting keyways in holes; and broaching square, hexagon, or other shaped holes, being the most practical and rapid tool for this work.

Will cut a ¾" Keyway in 1 minute.



KEYWAYS AND SQUARE HOLES BROACHED IN A MINUTE.

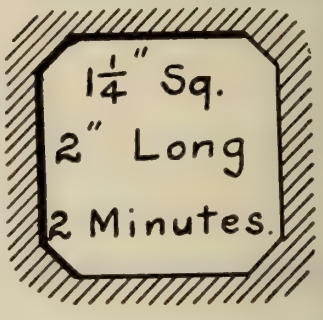
Square, Hexagon or any shape holes, Keyways, Spiral Grooves or any internal work can be done in less than 5 minutes on this machine.

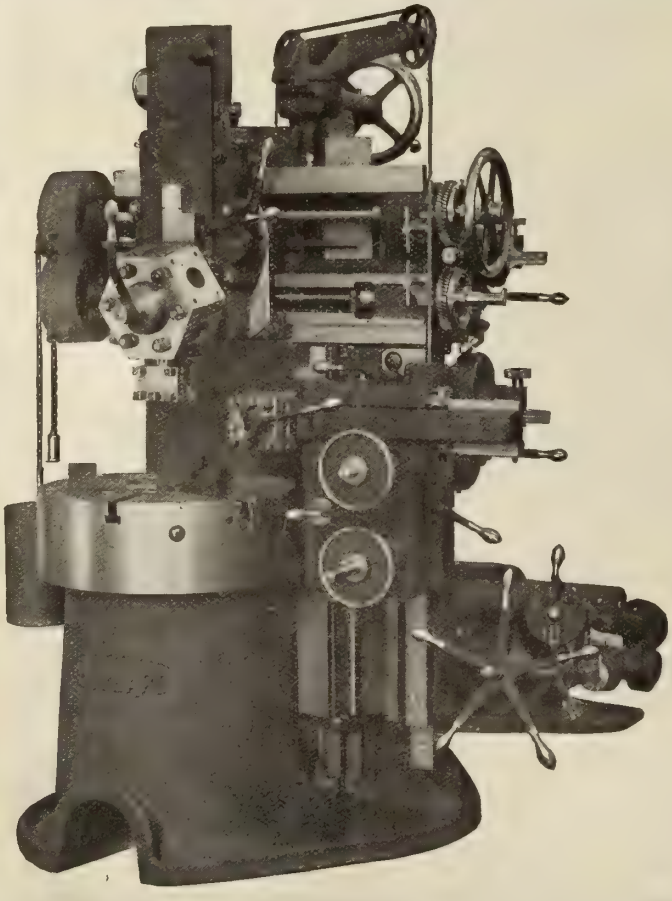
Write us and give description of your work.

The J. N. Lapointe Co.

MARLBORO, - - - - - MASS.

Will broach any size square hole.





You Pay for the Bullard Vertical Turret Lathe Whether You Buy It or Not

and the longer you wait, the more you pay.

IF YOU ARE NOT USING THIS MACHINE YOU PAY FOR IT, NEVERTHELESS, WITH THE MONEY LOST BY YOUR PRESENT METHODS OF PRODUCTION OF ALL FACE PLATE WORK WITHIN THE RANGE OF THE VERTICAL TURRET LATHE.

This loss is caused principally by wasted time.

The fundamental principle of the Vertical Turret Lathe is the "**elimination of wasted time.**"

Time between cuts is reduced by centralized control of the operation of the whole machine, as well as by rapid power traverse of all parts.

With both a Turret and a Side head, machining of several surfaces at once is possible—**MULTI-CUTTING.** And all the tools needed for a series of operations are held in instant readiness.

In all, every possible moment of the machine's and the operator's time is utilized and made efficient.

Ask for Treatise on Face Plate Work C-15.

Gridley Automatic Turret Lathe

For Rapid, Convenient and Economical Service

Work of greater length and more complex character than usual can easily be accomplished with the *"Gridley" Turret Lathe.*

The "Gridley" Differs

from all other automatics in the manner of supporting tools, and in the arrangement of the holders on the tool slides of the turret.

On all other automatics there is an overhang of the tool. This overhang prevents the performance of accurate work, because the method of supporting tools does not permit as heavy cuts or as coarse feeds. The "Gridley" Saves Money, as one operator can attend to several machines at once, and can use tools tandem.

We manufacture both Multiple Spindle and Single Spindle Automatic Lathes.

Write for descriptive catalogue.

The Morton Draw-Cut RAILROAD SHAPER

Built especially for the work.

Slots the Crown and Cellar fits in Axle Boxes better and quicker than a Slotter.

Planes the Brass Crown Bearing or Shell to fit.

Planes Shoes and Wedges, Rod Brasses, and is well adapted to general work.

Built in one size only—thirty-two inch stroke. Send for Bulletin No. 6.

We also build Standard Pillar Shapers of 26 to 30-in. stroke. Bulletins Nos. 4 and 5.

Special Shapers for Frog and Crossing work, Bulletin No. 10, and Locomotive Cylinder Planers with full equipment, Bulletin No. 7.

Built by the Draw-Cut Specialists,

The Morton Manufacturing Company

MUSKEGON HEIGHTS, MICH.

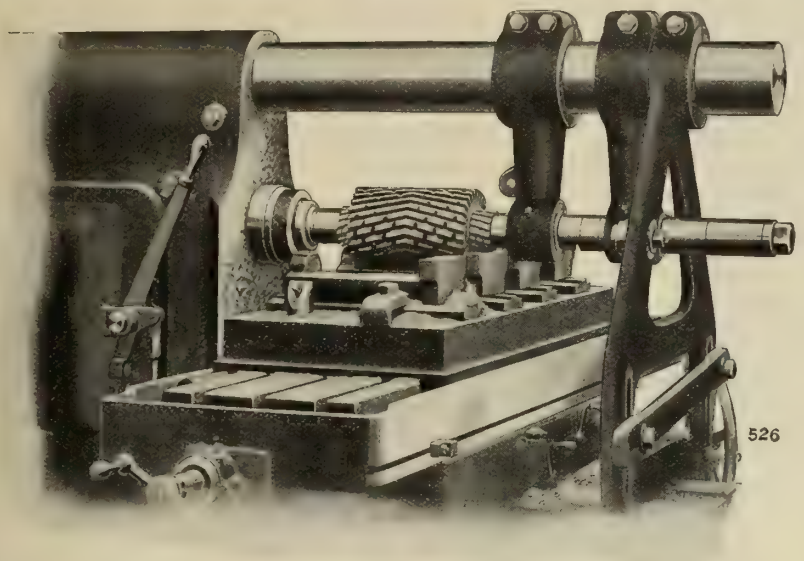
Do YOUR Milling the Cincinnati Way



THIS operation roughs out the inside of Cast Iron Vise Bodies. Total width of cut 15 inches; greatest depth 3-16 inch; length 6 inches. The largest cutter is 6 inches in diameter, 9⅝ inches face, runs 32 revolutions, feeding 4¾ inches per minute.

The pieces are held in a string jig—each one clamped independently. The milled pieces are removed as fast as traversed by the cutter, and others chucked in their places.

At the end of the cut the knee is lowered, the table returned, readjusted and a new cut started.

The operator then removes the last piece at the right-hand end of the jig and chucks a new one.

By this time the first one at the left has been milled, and he repeats the above process by again chucking new pieces behind the cutter.

Both the operator and the machine are busy all the time. Neither waits for the other. The only time lost is returning and readjusting the table, and the **TOTAL TIME PER PIECE IS ONLY 4¼ MINUTES.** Let us show you how to mill your work the Cincinnati way.

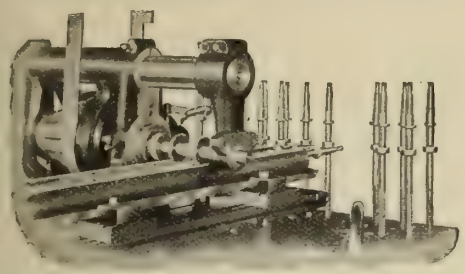
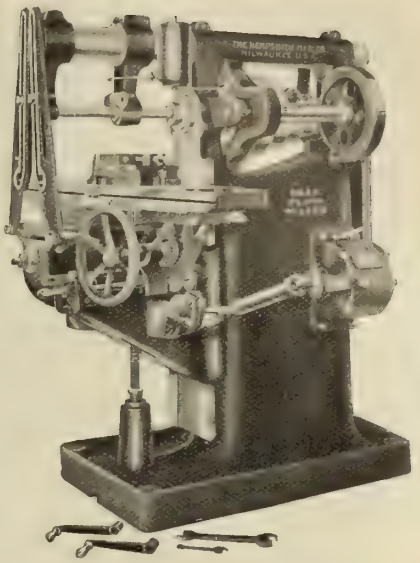
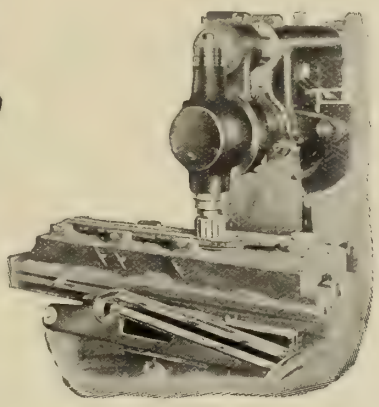
KEMPSMITH

No. 2-A Plain Miller

with its 36 *inch* Automatic table feed, extensive table surface, extremely rapid return, and concentrated operation, is an ideal manufacturing machine

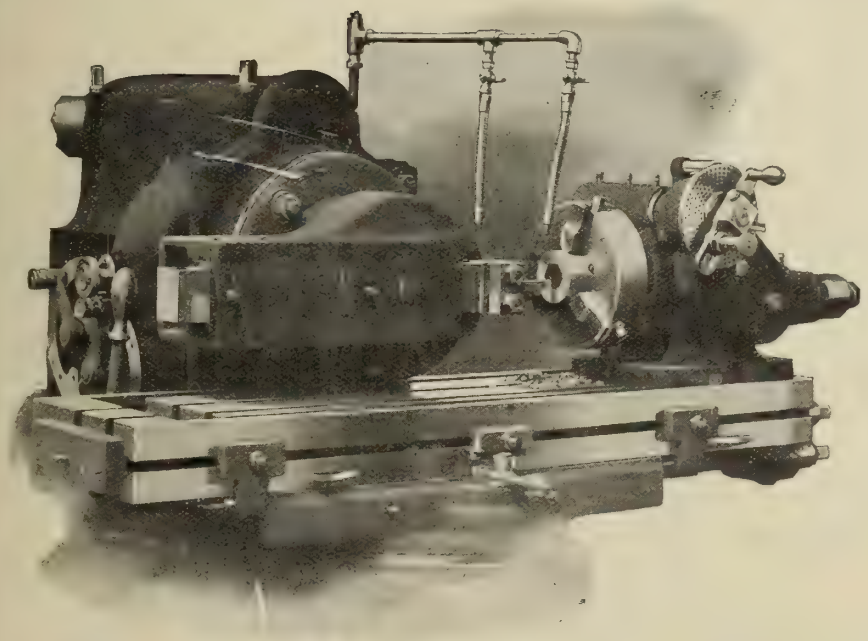






for keyway cutting, and long light cuts, and in duplicate manufacturing, in which quantities of small parts are set for one travel of the cutter, for cuts which are long, yet do not require a big powerful machine in proportion.

The KEMPSMITH MFG. COMPANY, Milwaukee, Wis.



EVERY tool room should have a Milwaukee Universal Milling Machine, every universal milling machine should have a slotting attachment and every tool room foreman should have our latest book—to be had for the asking.

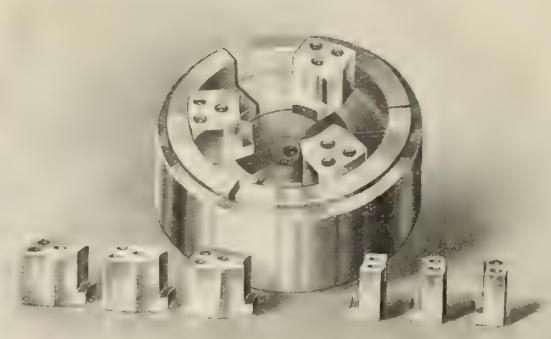
Heald Accessories—like Heald Grinding Machines—are Built for a "Single Purpose."



Draw-in Collet Chuck with 3 Sets of Special Jaws

The Heald Collet Chuck now furnished as standard equipment on all Heald Internal Grinding Machines is an example of the Heald Policy to make Grinders that are not only the most advanced in design and construction, but to fit them with every practical device to secure rapid and accurate work. Heretofore, the time required to chuck a piece for internal grinding has frequently been many times greater than the actual grinding time. The geared or scroll chuck in common use is slow to operate, soon becomes inaccurate through wear, clogs with dirt and grit, and requires frequent cleaning — also, each piece of work must be trued up separately, owing to inaccuracies in diameters and the varying pressures brought against the jaws. **All this takes time.**

The Heald Collet Chuck is a simple, substantial, quickly-operated device, controlled by a hand wheel at the end of the spindle, **that cuts down the time required for chucking operations to the minimum,** because it has done away with all the usual difficulties. The work is held in correct position, irrespective of slight variations in diameter, since the jaws all move uniformly and positively. It has, too, the additional advantage of taking special jaws to hold work of odd shapes that cannot be held in standard jaws.

The Heald Collet Chuck was designed especially for, and is furnished exclusively with, Heald Internal Grinding Machines.

Our Engineering Staff will take up your grinding problem if you wish it—no obligation on your part, but a fair, business-like investigation of conditions which may result in **dollar** profits to you where you now figure them in **cents.**

ACCURACY-EFFICIENCY-DURABILITY

"DETROIT" TWIST DRILLS

DETROIT DRILLS meet the ever-increasing demand for standardization and accuracy of measurements. We begin with the best quality "small tool" steel. Our tempering department is equipped with the most modern appliances for accurate measurements of temperature and is in charge of a recognized authority in the treatment of steel.

Each successive operation is submitted to the most rigid inspection, and each tool, in the making, must pass through the inspector's hands from three to eight times. The limit for variation permitted, in any but the larger sizes, is the one two-thousandth part of an inch.

"DETROIT" TWIST DRILLS run absolutely true from tip to shank, drill fast, and drill a maximum number of holes without regrinding. We make all kinds and sizes of drills, and will refund your money or provide new drills if they fall short of our guarantee when properly applied.

Write us the kinds and the quantity you use. We'll make you a proposition that will insure satisfaction to both of us. Catalog "R" is full of valuable information. Ask for it.

All "DETROIT" products are carried by live dealers everywhere.

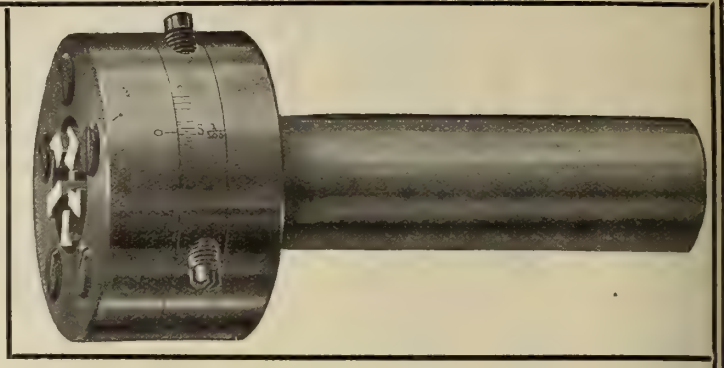
Geometric Adjustable Hollow Milling Tool



The Only Practical Hollow Milling Tool on the Market

Especially designed for Brass Finishing. Most serviceable and economical for reducing duplicate parts to an exact diameter prior to threading. Can also be used for light cutting on cast iron, steel or similar material. Not recommended, however, in place of roughing or finishing box tools for general screw machine work.

Extremely simple and durable. Easily adjusted. The cutters project beyond the face of the cam so as to permit of milling right up to a shoulder, where necessary.

We are prepared to furnish various styles of Geometric Adjustable Hollow Milling Tools, as well as special tools of this class to meet special working conditions.

Our Standard Hollow Milling Tools are furnished in sizes from 7-16 in. to 4 in. inclusive. Send us a sample or correct blue print of the work you wish to do, and we will submit quotations promptly.

INVESTIGATE OUR TOOLS, AND YOU WILL NOT BE DISAPPOINTED.

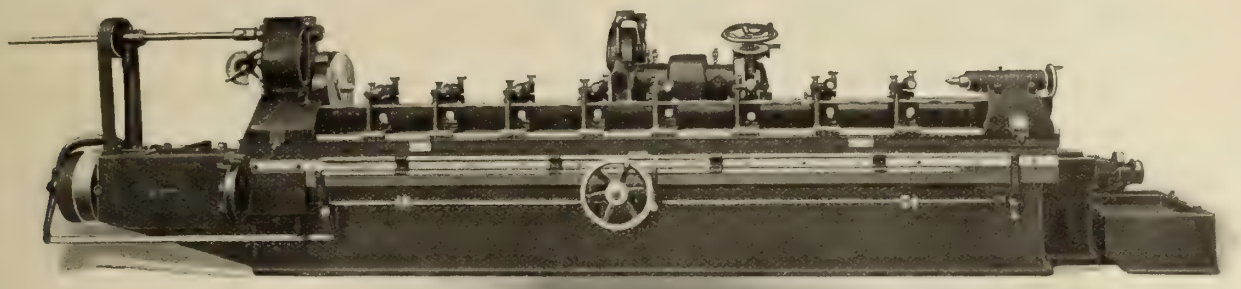
GRINDING ROLLS AND HEAVY WORK



Standard sizes: 20 in. x 96 in., 20 in. x 120 in., 20 in. x 144 in., 20 in. x 168 in.

These manufacturing machines are adapted for straight and taper cylindrical shafts, spindles, pistons, Corliss valves, plungers, tubing, and are especially desirable for grinding hardened steel and iron rolls.

Being designed as a self-contained machine without overhead obstruction makes them convenient for handling the work with a crane.

Send for Circulars, which give complete description.

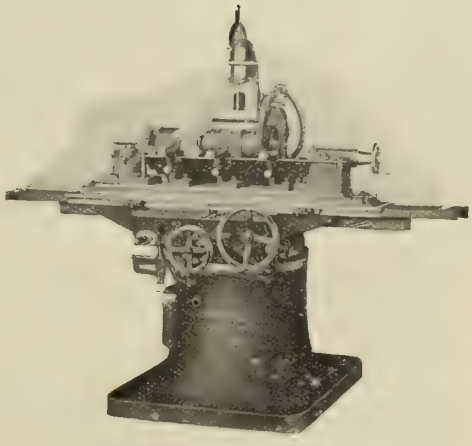
Business economy is only another term for profit—

Expensive, old-fashioned methods cannot compete with modern efficiency. You must make your profit through your savings in the cost of conducting business.

What about your cylindrical work finishing and sizing cost? Done on a lathe is profit wasted. This is an accepted fact. Time was, when finishing on a grinder was an experiment. It is now an accepted economy.

May we have the opportunity of proving the economies that the Bath Universal would effect in your business?



Arranged for Cylindrical Grinding.

High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

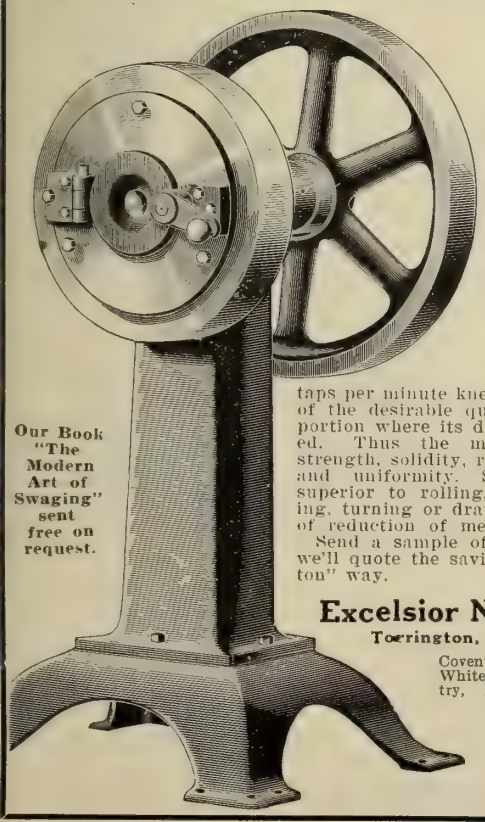
REDUCE METAL
WITHOUT WEAKENING IT



Swage The Dayton Way

The Dayton Swaging Machine does not sacrifice one particle of strength of the metal being reduced. From 2,000 to 6,000 taps per minute knead or squeeze all of the desirable quantities into the portion where its diameter is reduced. Thus the metal has added strength, solidity, rigidity, elasticity and uniformity. Swaging is far superior to rolling, grinding, milling, turning or drawing as a means of reduction of metal.

Send a sample of your work and we'll quote the saving by the "Layton" way.

Our Book "The Modern Art of Swaging" sent free on request.

An Absolute Necessity!

BLOUNT'S

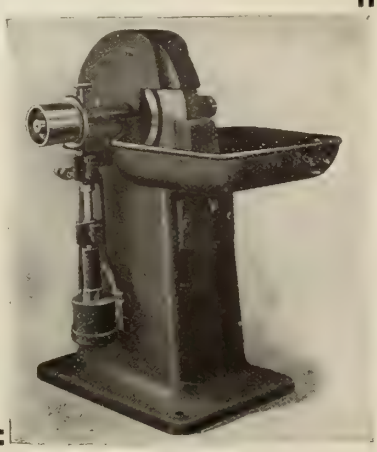
Wet Tool Grinder

This machine is the result of hard study and years of experimenting.

It requires so little power that it can be run continuously, if desired, at a saving.

Is fitted with self-oiling bearings, so that there is no wear of parts, as the propeller of the pump, furnishing a constant supply of water, is loosely fitted and does not touch the case at the nearest point. A sleeve cap prevents leakage without the use of packing.

Every up-to-date shop should have some of these grinders. **Absolutely guaranteed.**



WRITE FOR FULL PARTICULARS.

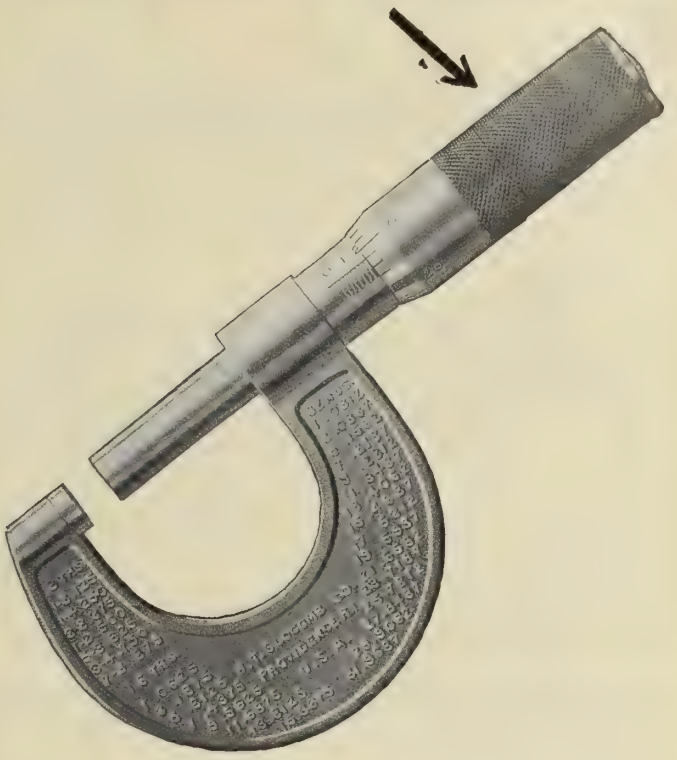
SLOCOMB MICROMETER No. 26 with FRICTION THIMBLE



Think this over

Have you ever known a fellow workman who owned a Slocomb Micrometer who wasn't proud of it? He knows that the adjustments in a Slocomb are worth something to him. It isn't a case of guess and try, it is a certainty. Then, too, he realizes that with the .270 diameter on the screw and anvil, the long thread for the screw to run in, the replaceable thread in frame, the absence of split shanks which attract dirt and wears the thread on the screw, the spring giving the thimble uniform friction, and the other features found exclusively in Slocomb Micrometers are worth while.

He realizes that these things mean a saving of money for him.

You can get the same benefits, for these features are in all Slocomb Micrometers, and every tool is guaranteed to be correct.

If you aren't now using Slocomb tools it will be worth your while to try some.

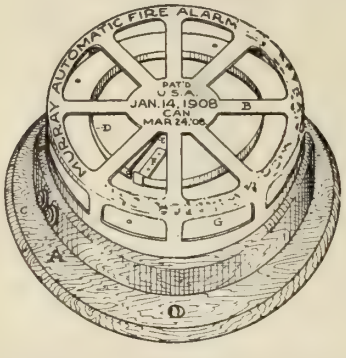
The Murray Automatic Fire Alarm



" Cheaper to have and never need, than to need *once* and not have."

Is a watchman that is always on duty and never goes to sleep.

Here's what a fire chief in one large manufacturing plant thinks of it:

The Murray Automatic Fire Alarm Co.
Toronto, Canada.

Dear Sirs:—

I have practically and thoroughly tested your Automatic Fire Alarm in every way pertaining to its use in factories and public buildings, and find it admirably adapted to the purpose for which it is intended, in effectively sounding the alarm.

Its simplicity and efficiency should at once commend it and secure its adoption and general use by those interested in automatic fire alarms.

JAS. CORBETT,
Fire Chief, Massey-Harris Co., Toronto.

The installation of this system is as simple as that of wiring ordinary call bells. Under the action of heat, when a predetermined maximum of temperature is exceeded, an electric circuit is closed and alarms given by the use of electric bells.

Write us for circular, and give us the chance to quote you price for your requirements.

IT PAYS TO BUY THE BEST

AIR HOIST!

The best may not be the cheapest but IT IS the most economical.

Economy is not effected by low first cost but by eliminating waste—waste of time; waste of power; waste of opportunity to promote production and, principally, waste of money, which is the sum of all other wastes.
You can cut out air hoist waste by installing Rand designs.
You save time because they are convenient and operate accurately.
You save power because the design and workmanship is the best on the market.
You save money because they last a life-time and give the best of service with practically no repairs.

BUY "RAND" HOISTS AND KEEP DOWN YOUR POWER AND REPAIR BILLS.

TRADE MARK

36 YEARS
AND GOING STRONG

Magnolia Metal commonly runs ten and fifteen years and sometimes twenty years, but here is a record that tops them all. Estimating nine hours as an average working day, the time that the Magnolia bearings have run in the Ice Machine mentioned below is equivalent to thirty-six years' service, and they are still running, in good condition.

THE BRYN MAWR REAL ESTATE CO.,
ENGINEER DEPARTMENT.

Bryn Mawr, Pa., May 13th, 1912.

Gentlemen:—

In answer to yours of May 8th, I wish to say that I have been using Magnolia Metal for about twenty years.

I have an Ice Machine on which the main bearings and crank pins were filled with Magnolia Metal **sixteen years** ago.

The Main bearings are still in first-class shape, but two years ago our Engineer tried to run without oil on the main crank, and we had to rebabbitt it.

This machine **runs continuously for five months** during Summer, and averages **eighteen hours a day the rest of the year.** The principal use I have made of Magnolia Metal is for bearings on Ice Machines, High Speed Engines, Air Compressors and bearings on some Pumps, and I find that it gives satisfaction wherever used.

Yours truly,
WM. SCHOCH.

W&B

"W & B" Wrenches Stand the Pull and Strain

All wrenches may look alike, But there is a difference. Just those fine points may be lacking necessary to make it the perfect tool.

YOU WILL SAVE BY USING "W & B" WRENCHES

They mean saving in freight when you can order all your Wrenches from one manufacturer.

They mean quality with a guarantee and a trade-mark backed by a Company with 58 years' manufacturing experience.

WHY HANG

to precedent and buy the same Wrenches because you have always done so?

IT IS TIME

that you learn what "W & B" Wrenches will accomplish for you.

IT DOES NOT PAY

to make expenditures for poor wrenches. You should consider

THE RECORD, REPUTATION

ability to produce, careful attention to manufacturing detail, and the character of the materials.

GIVE "W & B" WRENCHES A TRIAL AND TEST THEM

in competition with Screw and Drop Forged Wrenches of other makes. You will then realize that you have adopted the Wrenches that:

1. ARE MADE OF ABSOLUTELY PERFECT MATERIAL.
2. ARE CORRECTLY DROP FORGED, MILLED AND FINISHED BY EXPERT MECHANICS.
3. ARE CAREFULLY INSPECTED.
4. WILL MOVE THE STIFFEST NUT WITHOUT BREAKING.
5. SAVE THE COST OF RENEWALS.
6. ARE THE STANDARD OF QUALITY.

The same breaking strain test will convince you of their superiority, then avail yourself of the best Wrench quality and service.

WRITE US ABOUT YOUR WRENCH REQUIREMENTS.

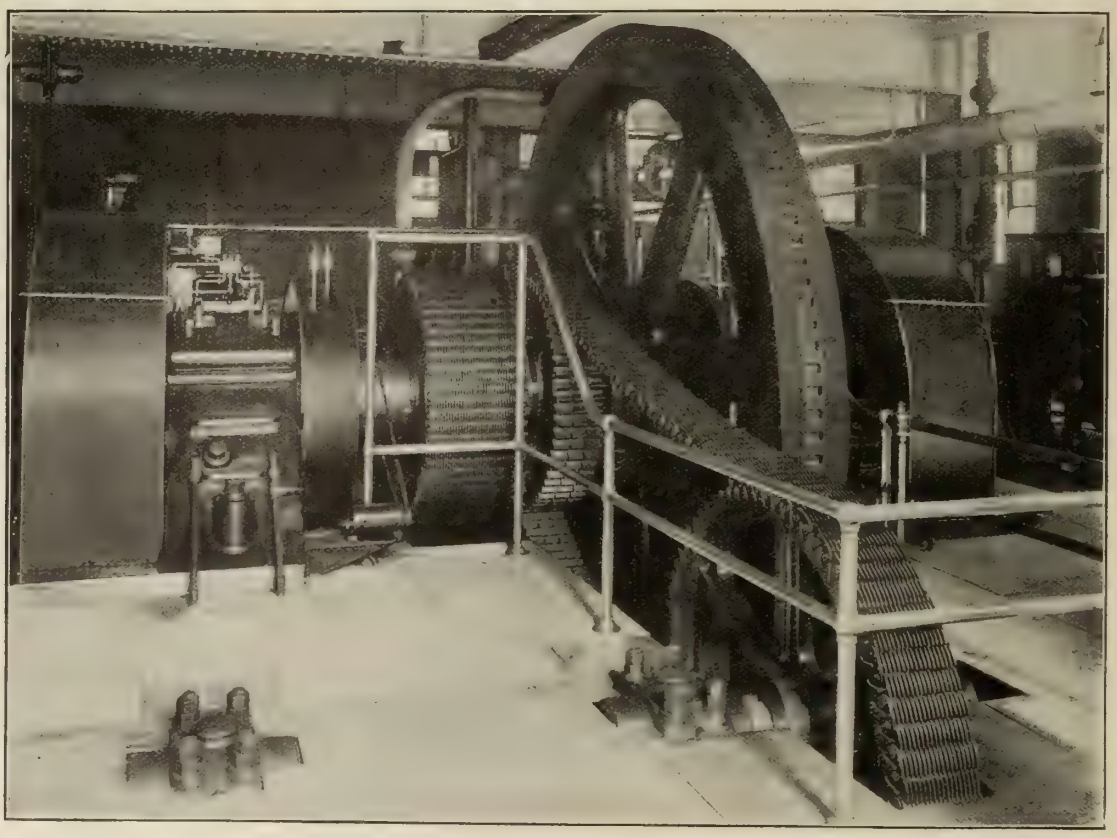
Morse Silent Chain
99% Efficiency

Morse Silent Chain
99% Efficiency



1000 and 500 horsepower Morse Silent "Rocker-Joint" Chains driving line shafts. Bulletin No. 1121 shows view of chains in motion, and some other large installations. Write for a copy to-day.

And why not ?

WE apply the word "best" to the Morse Silent Chain, not because "we believe" our chain best, but because all sorts of tests and years of service under all kinds of conditions have proved it far superior to all other chains.

We can't say it is the oldest chain. It's not. We *might* say more horsepower *is* in service. *There probably is.* But, neither of these points favor *any* chain.

We can say, however, the Morse Silent Chain alone has a "Rocker-Joint"; and, whenever an installation of any size, for any purpose, has been decided solely upon the merits and service performances of chains, the Morse Silent Chain has been accepted because it has *proved* itself "best," largely on account of this exclusive feature—the frictionless "Rocker-Joint."

Poor machines are made good, and good machines better by Morse Silent Chain Drive. Write us for Bulletin 1121.

Morse Chain Co., Ithaca, N.Y.

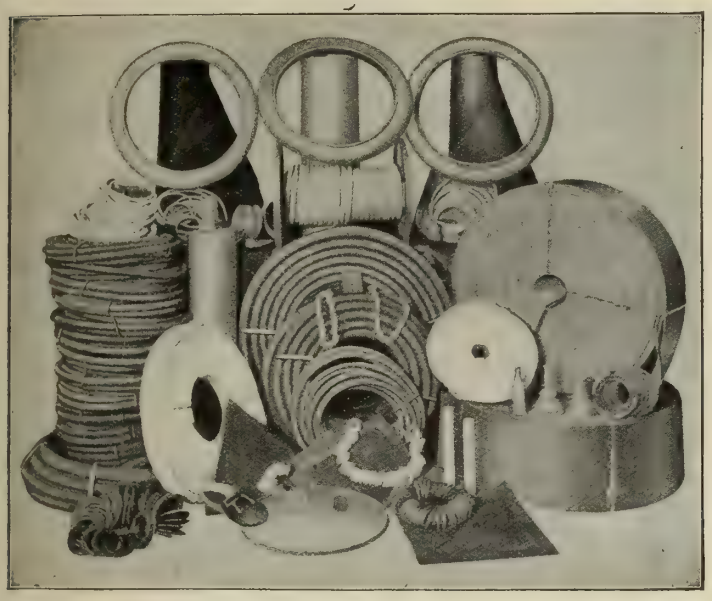
Power-Saving, High-Efficiency Belts

For Planers, Dynamos, Generators, Fan Work, Etc.



A few of the Lines We Manufacture.

Make your power transmission an ***asset*** instead of a ***liability***—a money-saver instead of a power-waster. Belt your machinery with

GOODYEAR

Imperial

High-Speed Friction Surface

Belts

"The Belt That Clings"

Built the famous Goodyear way, for high-speed pulleys where great tensile strength is demanded.

The Imperial has the cling of rubber and the endurance of many plies of hard-twist, long-fibre ***cotton fabric,*** rubberized, cured and vulcanized into one solid, enduring piece.

Earns Cost---Costs Less

The Imperial Belt is a power saver. It earns its cost by turning into increased production the power and the time lost by slippery leather belting. And it costs less.

Wears Longest Without Stretching

Most economical because it wears longest. First, because it doesn't slip. Secondly, because it is made by a process that abolishes ***internal friction.*** This soon wears the life out of best leather belting and is caused by internal ***grinding*** as the belt bends and whizzes around small high speed pulleys.

Instead of a few plies of coarse fabric, we build up the Imperial with many plies of fine fabric. After the ***stretch has all been taken out,*** rubber is forced through and all threads are separated from each other. Thus they can't rub and chew themselves, and the cause of internal friction is eliminated.

These belts are built to suit the purchaser. Let us quote prices on this most durable and economical high-speed, friction-surface, wear-resisting belting.

We also make other rubber products—Tires, Hose for all purposes, Sheet Rubber Packing, etc. Throughout, you get the same high quality materials, skillful workmanship and years of experience that have built such famous service into products of the Goodyear Tire & Rubber Co., Akron, Ohio, U.S.A. Write us at once.

Our sales of the last four months 50% greater than those of last year.

FACTORY HEATING and VENTILATION

BY

The Simplest and Most Economical System Known

THE

Sheldon Fan System

Consisting of

A Pipe Coil Heater, using exhaust or live steam, or both, which can be arranged for gravity return to a boiler located on the same floor.

A Blower, fitted with Sheldon Multivane Runner, which can be operated by any convenient power, most economically by a Direct Connected Engine, the actual operating cost of which amounts to only a small percentage of the heat in the system passing through the fan engine, the remainder being utilized in the heater, into which the engine exhausts.

Fan, Heater and Engine are centralized in one compact apparatus.

The Fan can be so arranged to take all or any part of its air supply from outside or inside the building, as desired.

The warm air is conveyed through ducts or flues and distributed throughout the entire building.

Let Us Tell You More About It.

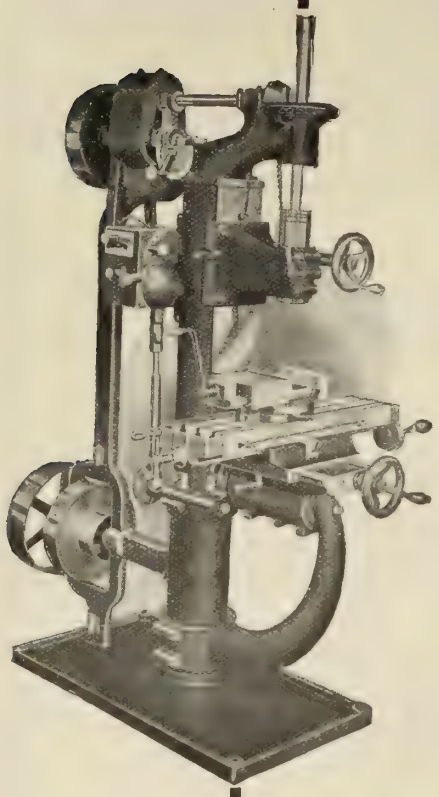
Head Office and Works: MONTREAL.

ST. JOHN TORONTO WINNIPEG VANCOUVER



You Need a Machine Like This on a Dozen Different Jobs

It's a No. 2 Knight Milling and Drilling Machine

This machine is very rigid, powerful and accurate, so that close work may be turned out with a high degree of satisfaction, and in the shortest possible time. The adjustments are quickly and easily made. On a large variety of work it is possible to make a saving of from 20 to 50 per cent. in time, as compared with other machines.

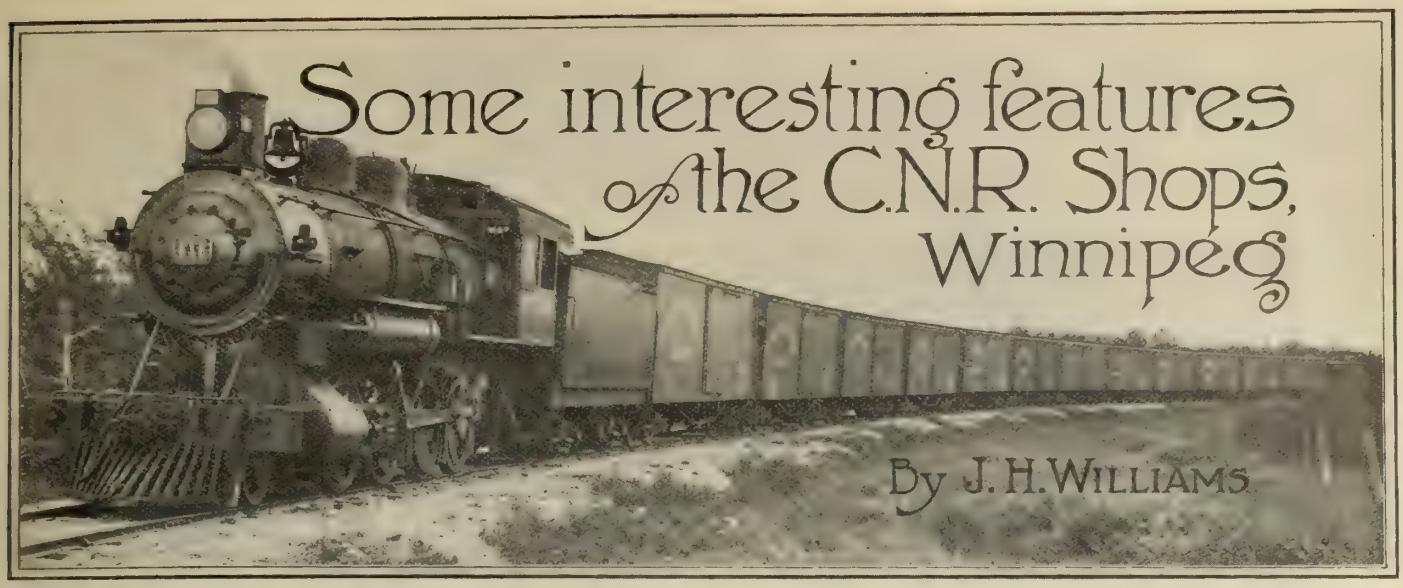
The fact that hundreds of Knight Machines are now in use in this and foreign countries proves that they are not experiments.

Briefly, the construction of the No. 2 Knight Miller is as follows:—Spindle of crucible steel, ground bearings; working surface of table, 29 x 8½ inches; feed, longitudinal and transverse; floor space, 60 inches; weight, crated for shipment, about 2,500 lbs.

WRITE US ABOUT IT TO-DAY.

The Canadian Fairbanks-Morse Co., Limited

MONTREAL, ST. JOHN, OTTAWA, TORONTO, WINNIPEG, CALGARY, SASKATOON, VANCOUVER, VICTORIA.



Some interesting features of the C.N.R. Shops, Winnipeg

By J. H. Williams

THE Canadian Northern Railway locomotive shops at Winnipeg are engaged exclusively on repair work and rebuilds, and turn out on an average from 35 to 40 engines per month. This includes heavy repairs, general repairs, wrecks and rebuilds. In addition, there are usually several steam shovels, pile drivers, etc., under repair month by month.

The erecting, boiler, tank and machine shops are all in one building, 650 feet long by 200 feet wide, divided into three bays, two of which are 75 feet and one 50 feet wide. The two outer bays are of the former width, while the 50 foot bay lies between them. The south bay (75 feet) forms the erecting shop and contains twenty-six transverse pits, pitched at 22 feet centres. One of these, near the centre of the shop, is the hoist pit, over which is located a 125-ton wheeling crane. The erecting shop is also served by three hand operated 2-ton travelers. Engines are brought to any desired pit by an 85 feet electrically operated transfer table, which also serves the car shop. They are brought in, pilot end first, so that the front end is towards the machine shop. This enables tubes to be handled by the 7½ ton traveler in the adjacent bay—a very convenient arrangement. The same traveler also assists in erecting front end work, the erecting shop pit tracks being extended 15 feet into the machine shop for this purpose.

Extending the full length of the shop is a large galvanized iron suction pipe, clearly seen in Figs. 1 and 2. This pipe is connected to an exhaust fan and has at each pit a vertical branch extending down between the crane runways of the erecting and machine shop bays. When ready for steaming, the engine stack is coupled up to this vertical branch by a short connecting length and the exhaust fan quickly draws up the fire, at the same time removing all smoke through the roof.

Every appliance is to be found here for expediting work and cutting down costs. Needless to say, an engine is never stripped for a cracked frame if thermit can be used. Figs. 3 and 4 show an exceptionally large thermit weld made in these shops. The weld was 25 inches in length, being something unusal in locomotive repair practice. It was made in the usual way, a matrix of wax being built up to the exact shape desired for the reinforcement. The weld, besides being 25 inches long, was 3 inches thick, necessitating the use of two crucibles, each holding 100 lbs. of thermit, 10 lbs of mild steel punchings and 2 lbs of manganese. Fig. 4 shows the pouring gate which was 32 inches long. Only one riser was necessary. Naturally, in welding so large a section, great care had to be taken when preheating to equalize the temperature and bring all parts of the section to a uniform red heat. Great precautions were also necessary in making allowance for expansion and contraction. However, all these obstacles were successfully overcome and the weld turned out perfect in every respect. We are indebted to the Goldschmidt Thermit Co., New York, for the use of the two cuts illustrating this weld.

Machine Shop.

The centre (50 ft.) bay is devoted chiefly to the heavy machine tools and to wheel work. All machines in this bay have individual motor drives, power being purchased from the Winipeg Electric Railway Co. The equipment here includes a 90-inch vertical boring mill, 24-inch slotter, horizontal boring machine, 60-inch planer. Bertram coach wheel lathe, 36-inch slab miller, and a 42-inch heavy duty engine lathe. There are also five smaller heavy engine lathes, two Niles driving wheel lathes, a 300 ton hydraulic wheel press, etc., etc. All tire work is done in this bay. At present the tires are heated by gasoline in pipe rings; but crude oil furnaces having a capacity of six tires are about to be installed.

In fig. 6 is shown one of the interesting labor-saving devices developed in these shops. The illustration shows the

Fig. 1. Erecting shop looking west. Hoist pit in the foreground.

*Associate editor, Toronto.

method used for placing wheels in the Bertram coach wheel lathe; without employing the overhead traveler. A plain bar is bent into a V-shaped yoke (A), its two arms being hinged to lugs on the lathe bed. At its outer end it is loosely attached to a simple crosshead (B) which is operated through a stout piston rod by an air cylinder below the floor. The device is here shown in its elevated position; when the air is exhausted the piston falls until the crosshead rests upon the floor. The wheels and axles enter the shop by a track parallel to the lathe and not seen in the illustration. When the wheels are opposite the lathe a pneumatic pit jack engages with the axle and raises the wheels from the track. They are then swung round parallel with the lathe and run across the floor until the axle is just beyond the crosshead (B), which of course is resting upon the floor. Air is now admitted to the cylinder and the yoke (A) raised, lifting the wheels from the floor. The axle is now rolled along the yoke and the wheels enter the lathe. Any endwise adjustment is easily made by means of the small rollers (C) which are attached to the yoke. To operate this device, two 8-inch Westinghouse air brake cylinders are used, one being bolted on top of the other to give sufficient length of stroke. As may be seen, the lathe was in use at the time this photograph was taken; so that it was not possible to show the segment of the large gear wheel removed and a pair of wheels about to enter. However, no difficulty will be found in grasping the idea from the above description.

Fig. 7 shows the 60-inch planer in this bay set up for planing shoes and wedges, one head planing the inside of the castings, while the other planes the outside of another set of castings. For planing the inside, the shoes or wedges, as the case may be, are placed in a long trough-section casting (D) which has a tongue fitting the slots of the planer table. Set screws through the side of this trough securely clamp the shoes, which then have the inside of both cheeks planed simultaneously by the tool (A), which is of the exact width required. For planing the outside, the work is set up on blocks as seen at (B) and bolted to the table in the usual way. The tool for this operation is seen at (C) and in greater detail in fig. 8. To relieve the tool on the reverse stroke of the planer, each arm has a knuckle joint swinging on a substantial pin, the construction being clearly seen in fig. 7. The two arms are not quite parallel, being set in about ⅜ inch at the points. This makes the tool act in the same way as if the head of the planer were swung over, and thus does away with the drag of the tool

Fig. 3. Thermit weld. Crucibles and Mould Box in position.

Fig. 4. Thermit Weld, showing gate and reinforcement.

Fig. 2. Erecting shop, looking east.

on the back stroke. The output of shoes and wedges from this planer is about 26 per day.

75 Ft. Bay, Brass Room, Etc.

The brass room is located at the bottom of the 75 ft. bay of the machine shop and is divided off from the main shop by a wire screen. It is excellently lighted, and while not large, is well equipped for turning out work rapidly and economically. The brass-working machinery is all of modern design and includes, among other items, six lathes (turret and plain), 25-inch drill press, buffing wheels, tool grinder, etc., etc. The rest of the 75 ft. bay is taken up by bench and machine work. One part is used exclusively for manufacturing purposes (shop order work). The machines in this department include a 42-inch Niles boring mill, 42-inch Bertram ditto 24-inch Bertram ditto, triple head bolt cutter, four iron working turret lathes, and a Bertram 4-spindle drill, chiefly used on arch bars, draw bar pockets and other car work.

The motion gang is an entirely self-contained department having all the necessary equipment for carrying out this class of work. Nearby it is a gang handling all air brake, injector and lubricator work, while in the centre of the bay there is a group of machines for general purposes. The driving box and rod gangs are provided with a hydraulic press, 24-inch and 40-inch boring mills, 18-inch and 24-inch lathes, 18-inch double head shaper, 36-inch planer, 18-inch slotter, heavy duty drill, etc. The machines are arranged in such order as to reduce handling to a minimum, the work passing straight along from one machine to the next and being finished on the last. Engine trucks are repaired on two elevated tracks standing about 2 feet above floor level. This enables men to get below the trucks and generally makes for convenience in handling. The trucks are placed on the elevated tracks by one of the two 1½ ton electric travelers which serve the whole length of this bay. All the more important machines are fitted with handy jib cranes made on the premises from 6-inch channels and 4-inch pipe. In this way a great deal of lost time due to waiting for the overhead traveler is eliminated.

Fig. 5. Heavy Tool Bay of Machine Shop, looking east.

The Tool Room.

The tool room is located in an annex about half way down the north bay of the machine shop, and is a thoroughly well equipped department. The machines, walls, shelves, racks, etc., are painted white in order to obtain the maximum value of the natural lighting, which is provided by windows on two sides of the room. Fig. 9 gives a good idea of the bright appearance of the shop. It is the intention, in the near future, to build an addition to the tool room and instal a forge and hardening furnaces. At present, lathe and planer tools, etc., are forged in the blacksmiths' shop, whence they are taken to the tool room to be rough ground dry to standard shapes. This is done on the Sellers No. 1 tool grinder seen in the foreground to the right of Fig. 9. The tools are then returned to the smith to be hardened, after which they are again sent to the Sellers grinder, where they are wet ground to finished shape and afterwards delivered to the tool store. This process is considered to be more economical than hardening the tools immediately after forging, as the smith does not have to forge so accurately to size and the tools are more quickly ground. All lathe, planer, shaper and slotter tools are of high speed steel.

For sizes below ½ inch and above 1½ inch, carbon steel twist drills are used, while drills between these two sizes are of high speed steel. They are ground on a Yankee drill grinder, one man having sole charge of this work. He also grinds all chisels, flat drills, etc., and keeps in order the emery wheels throughout the machine shop, visiting each grinder twice a day. A second Yankee drill grinder has been fitted up with a special spindle and is used for general grinding. There is also a No. 2 Brown & Sharpe universal grinder on which saws are sharpened, some of them as large as 30 inches diameter. The large sizes are, of course, ground in a horiz-

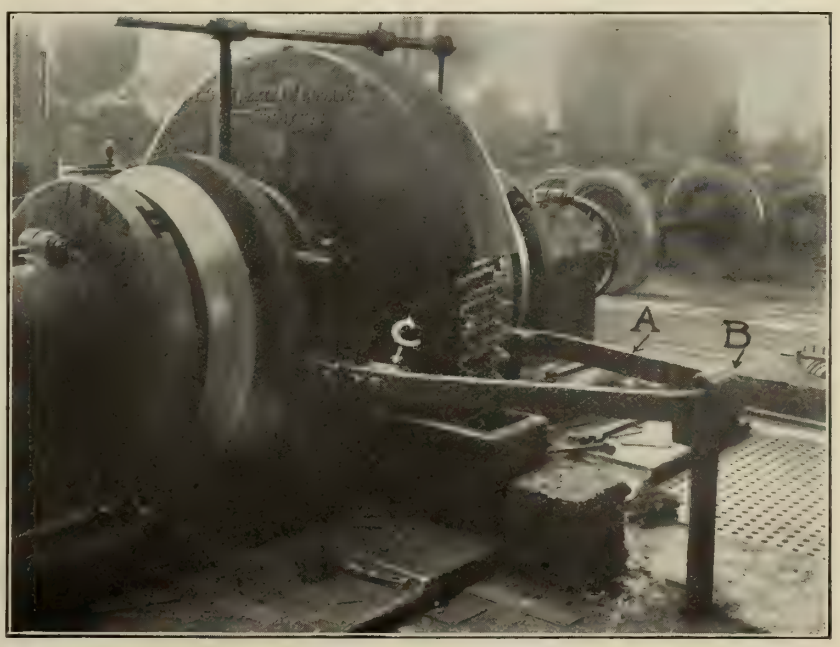


Fig. 6. Method of running truck wheels into Bertram Coach Wheel Lathe, without using overhead travelling crane.

ontal position. This B & S grinder is used on all reamers, rose bits, end mills, etc., and is fitted with an internal grinding attachment.

Further equipment includes one 12-inch and one 16-inch Pratt & Whitney tool room lathe with taper turning and relieving attachments; Canada Machinery Corporation 18-inch by 6 feet engine lathe; 16-inch Flather shaper; Q & C power hack saw; 20-inch Davis drill press; and two No. 3 milling machines. Of these two millers, one is a Brown & Sharpe, and the other an R. K. Le Blond.

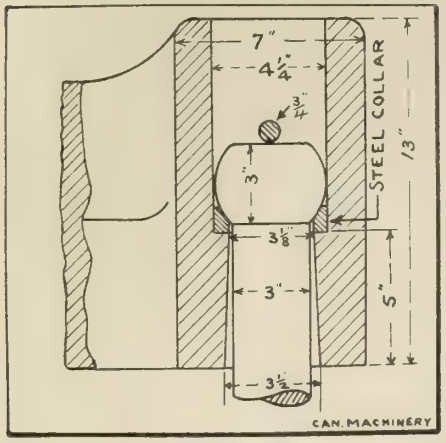

Fig. 12. Attachment of Piston Rod to Flanging Clamp.

Milling Beading Tools.

The Le Blond miller is seen in Fig. 10, set up for milling flue beading tools in batches of a dozen at a time. In some shops these tools are milled one at a time, being gripped in a machine vise for the purpose, but in the Canadian Northern shops, a much more expeditious method has been devised and is here illustrated. The beading tools are first rough forged to gauge, as shown at (A), and are then set up, twelve at a time, in the fixture seen on the milling machine table. The bar (B) serves as a gauge against which the face of each tool is set before being finally secured by the set screws in the clamping bar. By removing the set screw (C), the gauge bar (B) may be swung down out of the way. The table is then raised and the tools are milled by the gang cutters shown. A finished tool is shown at (D).

Fig. 11. Air-operated Flanging Clamp in Boiler Shop.

The machines in the tool room are all operated from line shafting, the latter being driven by a 15 H.P. motor. One corner of the room is given up to belt and hose repairs, while in another are the lockers for the men's clothes, etc.

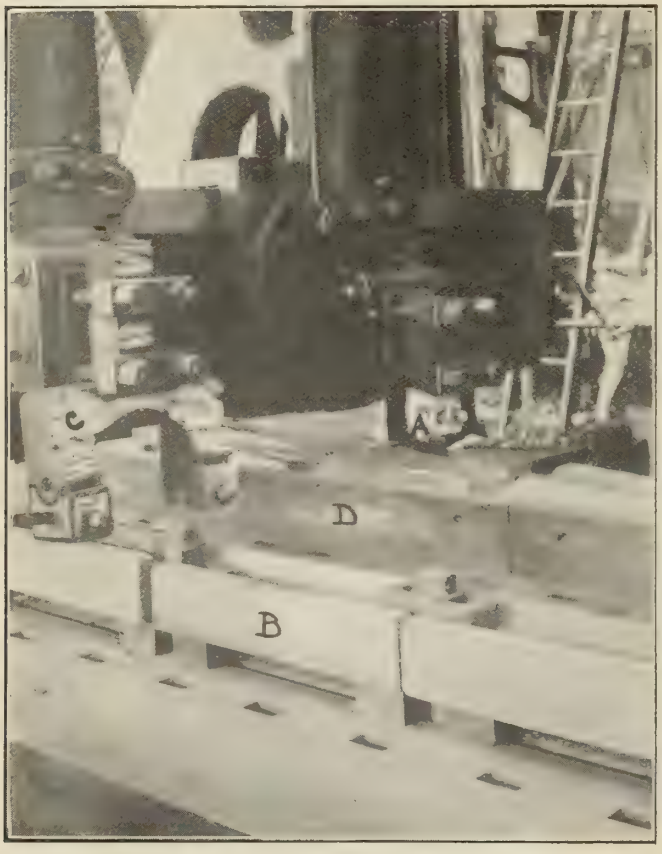

Fig. 7. Planing Driving Box Shoes in batches. One head planes the outside and the other the inside.

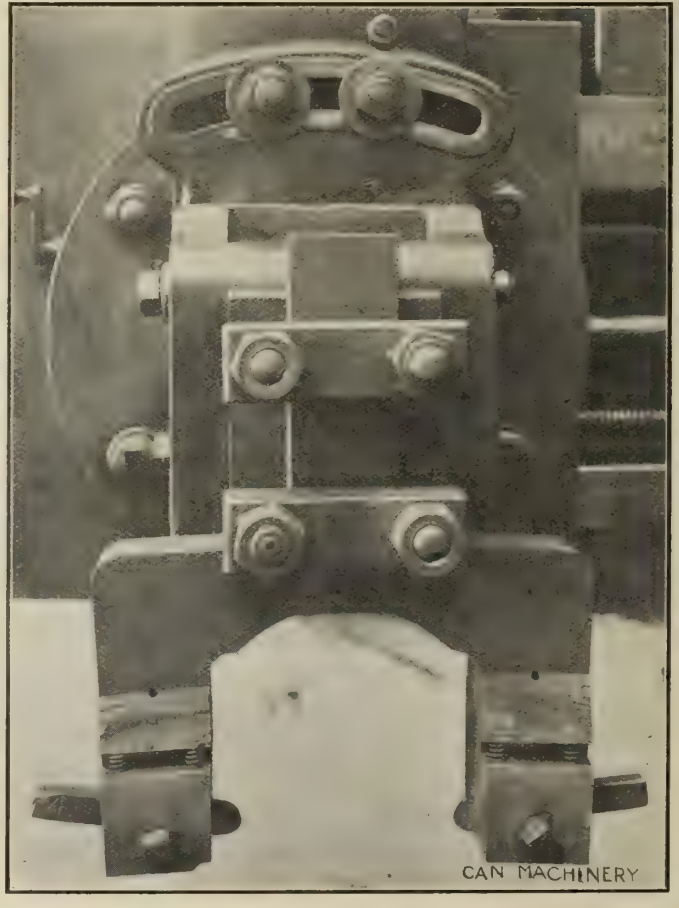

Fig. 8. Detail of planer tool for outside of shoes and wedges.

A third corner—that seen in Fig. 9 – is used for the repair of pneumatic tools used in the erecting shop, boiler shop, car department and roundhouse. One man devotes his entire time to this work. The air motors are all numbered and are brought to the tool room in rotation, two from each shop daily. They are examined, oiled, and, if necessary, repaired. In this way, all motors are kept in good shape, enabling them to work at their maximum efficiency.

Dies for bolt cutters and pipe threading machines are all made from high speed steel. They are threaded by a hob in the machine in which they will eventually be used, thus ensuring absolute accuracy. When hardened and finished they are fyled away in very convenient racks, which enable the dies for any given machine to be immediately identified. A large number of special tools, jigs and fixtures have been devised in this tool room, but considerations of space forbid their description. Outside the tool room is the tool store where all tools are given out on check.

Boiler and Tank Department.

The east end of the two bays of the machine shop is given over to boiler and tank work, the equipment including large Bertram double punch and shear; single ended punch for tank work; large crude oil flanging furnace, Bertram horizontal punch; Lennox rotary bevel shear; small hand clamps for ashpan work; pneumatic flanging clamp, etc., etc. All the machines are fitted with individual jib cranes and air hoists, as is also the flanging furnace.

All plate work is flanged by hand, the shops not being equipped with a hydrau-

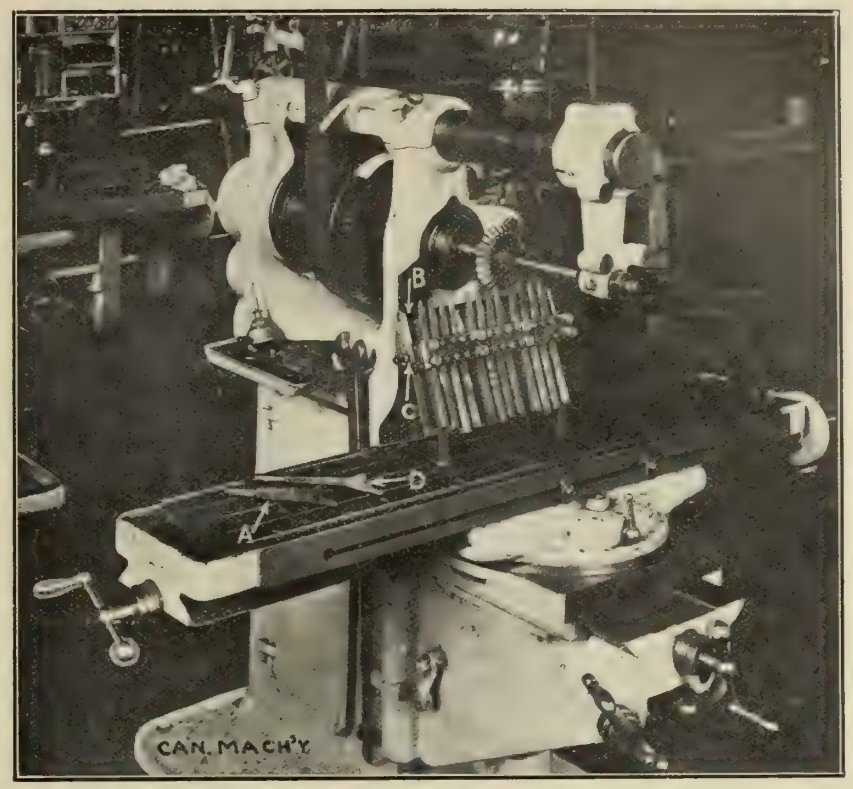

Fig. 10. Milling flue beading tools in lots of twelve at one setting.

FIG. 9. GENERAL VIEW OF INTERIOR OF TOOL ROOM.

lic flanging press. The clamp shown in fig. 11 is used for holding plates during flanging, and is another of the many ingenious home-made devices got out in these shops. It is operated by air, there being two 20-inch cylinders below the

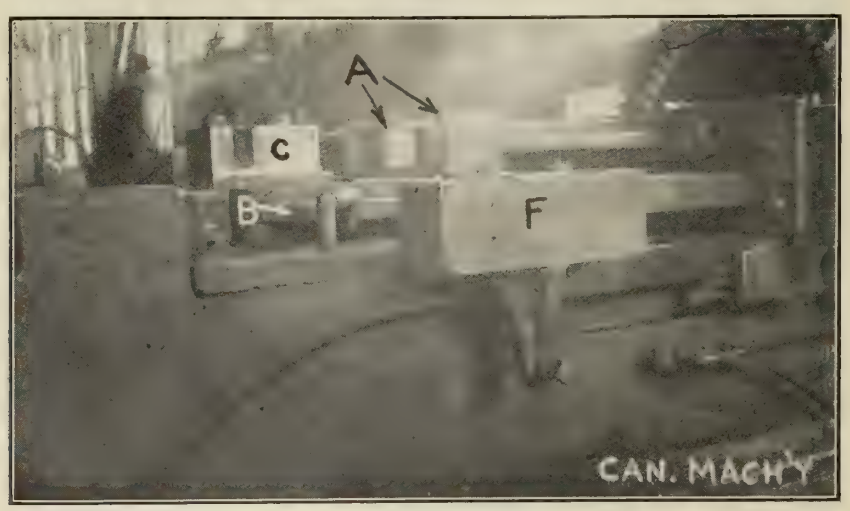

Fig. 13. Bulldozer set up for making Drawbar Pockets.

floor, bolted to the lower jaw of the clamp, one at each end. The piston rods are 3 inches in diameter, balled out at the top to a diameter of 4¼ inches. The holes in the jaws of the clamp are 3½ inches, those in the top jaw being counterbored to suit the balled heads of the piston rods. A ¾ in. pin serves to raise the clamp. Fig. 12 shows the arrangement, and from this it will be seen that the top jaw is free to adjust itself evenly upon the work. The clamp is used as follows in the case of a front flue sheet. The flanging block is balanced on the lower jaw and the heated plate placed upon it. Air is then admitted to the top side of the two pistons by means of a three-way valve operated by the handle seen on the right. The flue sheet is thus held securely to the block during the process of hand flanging. The clamp is also used for pressing out cylinder head casings, piston valve chamber casings and air reservoir heads; in fact it has almost as many uses as a hydraulic flanging press. The shop air system carries a pressure of 110 lbs. per sq.. inch, which enables the clamp to exert a pressure of about 34 short tons.

The boiler and tank departments, being situated at the extreme end of the shop, have a separate tool store of their tapped off the supply line and enters below the piston, which is packed with a cup leather. The piston rod is thus pushed outwards from the top end of the cylinder, the thrust being taken in the usual way by a plank or an "old man."

Heating and Lighting.

The main shop and tool room are heated in winter by direct radiation from live steam pipe coils attached to the walls between the doors and windows. This system is probably the best in a plant such as this, where the erecting shop is served by a transfer pit. The frequent opening of the side doors allows large quantities of heat to escape, and the live steam coils warm up the shop again more rapidly than does the indirect system of radiation in which heated air is distributed by fans. At all events, such is found to be the case here. The round house in connection with this plant is heated by the indirect system and it is found almost impossible to keep up a comfortable temperature in severe winter weather.

General artificial illumination is by Cooper-Hewitt mercury vapour lamps, in addition to which connections are provided for incandescent lights and extension cables to each machine and also for the erecting shop pits.

The Blacksmith Shop.

The blacksmith shop is adjacent to the west end of the machine shop, being divided therefrom by a brick wall. Material is handled between the stockyard, blacksmith shop, machine shop and stores by a complete system of industrial tracks, which extend also to the car shops, since the smithy serves both departments. There are twenty-five fires, all provided with hoods, leading to a large overhead flue from which the gases are drawn by an exhaust fan. The three steam hammers, of 2,000 lbs., 1,500 lbs. and 1,000 lbs. capacity respectively, are conveniently placed for the various classes of work, and are grouped around a central jib crane which serves them all. In addition to these, there is a Beaudry trip hammer, with oil furnace, for all light work.

The principal heavy equipment consists of one heavy punch and shear, one 1½ inch Acme bolt forging machine, one 3-inch Acme forging machine, Bertram bulldozer and a Newton cold cut-off saw. The machines are all served by crude oil furnaces. The forging machines are so placed that work passes direct from them to two triple-headed bolt cutters, and thence, by small cars on the industrial tracks, to the stores.

Spring Department.

One corner of the shop is set aside for spring work. This department is equipped with an Evans' spring punch and shear; a pneumatic roller for giving camber to the plates; a nibbler; screw clamp for use while putting on bands; tempering furnace and quenching tank. Much time is saved in spring tempering by heating the plates only once. They are brought to a hardening heat and then cooled off (not quenched) in oil, until their temperature is reduced to the flashing temperature of the oil. From this point they are allowed to cool off in the air; so that hardening and temper-

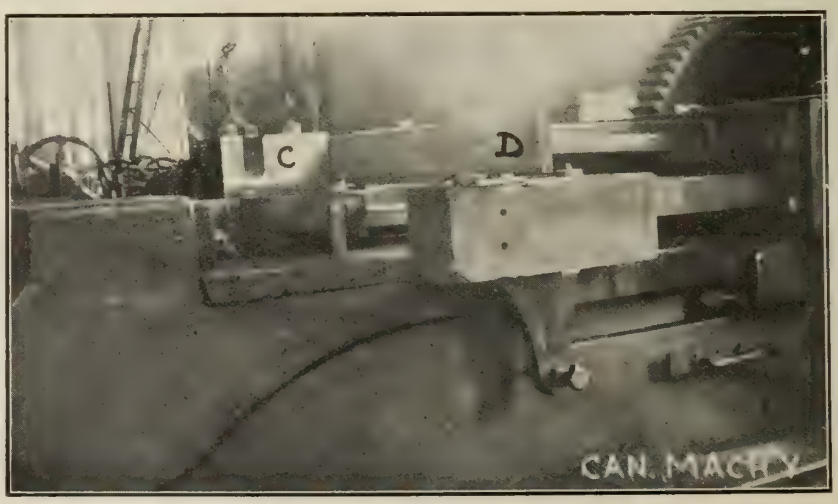

Fig. 14. Making Drawbar Pockets. The heated bar in position for first operation.

ing may be said to be accomplished at one heat.

Making Draw-bar Pockets.

One of the interesting jobs done in this shop is the making of draw-bar pockets complete at one heat on the Bertram bulldozer. This is done in two operations, the first one forming the pocket, while the second turns in the lips and cuts them off to length. Fig. 13 shows the dies set up for the job. There are two sets of dies and rollers, the upper (A), performing the first operation; while the lower (B), performs the second. As may be seen in fig, 14, the heated bar (D) is first placed across the upper dies; the head of the machine then advances and the rollers (A), fig. 13, together with the casting which carries them, force the bar round the die (C). The distance between the rollers of course corresponds to the outside width of the pocket, while the die (C) is the same width as the inside of the pocket. The operation of forming the lips has now to be performed. The pocket is lifted from the upper dies and turned end for end, so that its open end faces the moving head of the bulldozer. It is then placed in the lower dies, which, as the head advances, form the lips, while at the same time two shear blades trim them off to length. The way in which this is done will best be understood from a study of fig. 16, the reference letters corresponding with those on fig. 13. The finished draw-bar pocket is shown at (E), fig. 15. In some shops it is necessary to take two heats for this job, or else set up the dies for the two operations on two adjacent bulldozers. It will thus be seen that the method here described effects a considerable saving of time and money.

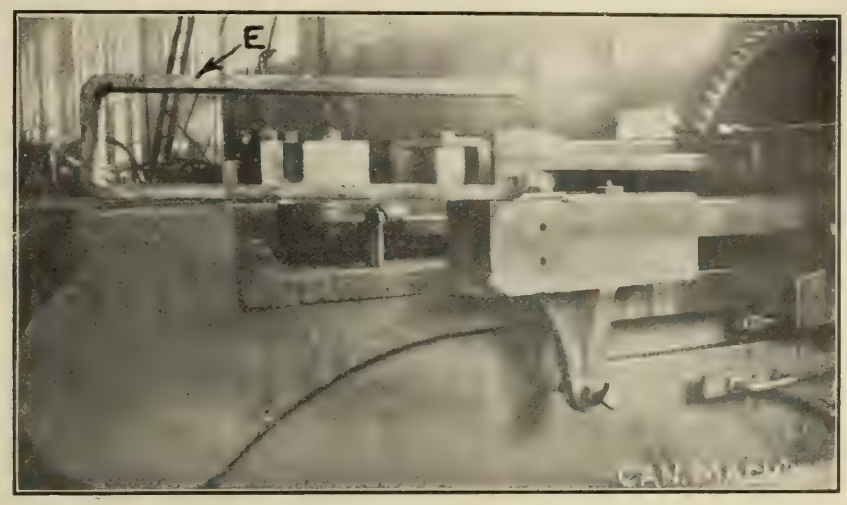

Fig. 15. The finished Drawbar Pocket—seen at (E).

The Grey Iron Foundry.

The foundry is a brick building of three bays, and is 150 feet long by 90 feet wide. The natural lighting is exceptionally good, but otherwise there are no special features to be noted. As is usual the centre bay forms the main molding floor, being served by a 10-ton electric traveling crane. Of the two side bays one is used for the smaller molds, while the other is occupied by the core-making department. There are two core ovens, one being used for small cores, and the other for larger cores and dry sand molds. The foundry is equipped with three Pridmore molding machines, used chiefly on grate bars, stake pockets, queen posts and general car work. No brass castings are made, the company purchasing all such from outside firms.

There are two Whiting cupolas, of 46 inches and 62 inches diameter respectively. Blast at 11 oz. pressure is supplied by a No. 8 Sturtevant fan, belt driven by a 30 h.p. motor. Pig, scrap and coke are raised to the charging platform by a hydraulic hoist. About 16 molders are employed and a cast takes place every day, the average output be-

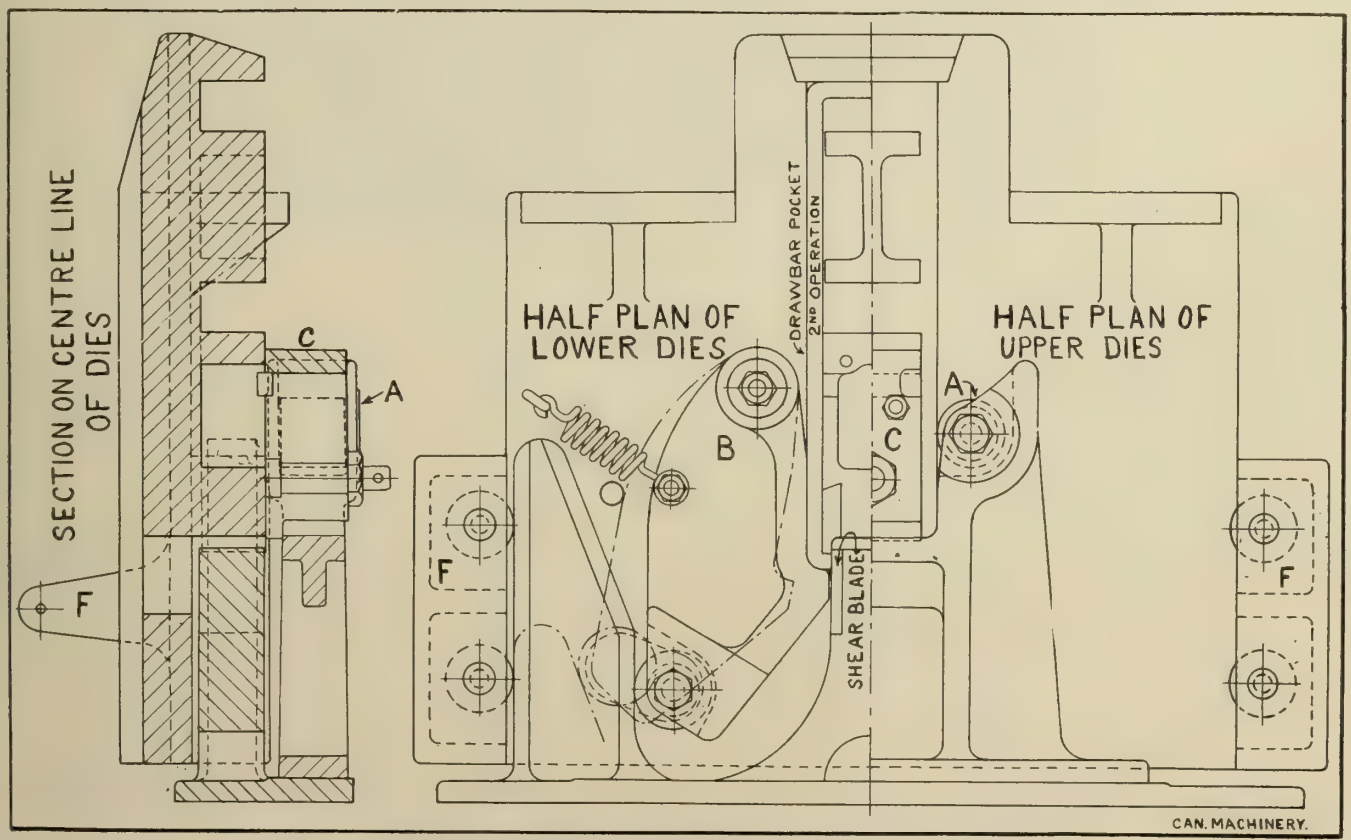

FIG. 16.—DETAIL OF BULLDOZER DIES FOR MAKING DRAWBAR POCKETS.

ing about 175 tons a month. The cleaning room contains two tumbling mills and the usual outfit of grinding wheels, etc. Pneumatic chipping hammers are used exclusively, the foundry being piped for compressed air.

General Remarks.

The car shops carry out repairs only. Extensive alterations and additions are about to be made to them, so that we reserve their description to a future occasion.

We are indebted to A. H. Eager, superintendent of shops, for facilities granted us in securing photographs; and to D. M. Galloway, general foreman, and A. Hopkirk, shop engineer, for particulars of the various jigs and devices described in our article. We hope to illustrate more of these at an early date.

MOTOR TRUCK WITH HYDRAULIC TRANSMISSION.

A MOTOR wagon weighing five tons, fitted with a system of variable hydraulic transmission, having as its basis a pump invented by Dr. Hele-Shaw, was the subject of a recent demonstration by Messrs. Campayne, Limited, 64 Victoria street, S.W., London, England. In this vehicle, the petrol engine is coupled direct to the pump, and the two motors, which are incorporated with the driving wheels, are actuated by oil which is forced through them and returns to the pump in a closed circuit. The pipes which convey the oil converge on a universal joint about the middle of the chassis and serve as radius and torque rods, and there is no flywheel, clutch, change-speed gear, or differential.

Operating Features.

Alterations in speed are effected by altering the stroke of the pump, which is of the rotary plunger type. It consists of a cylinder body, with seven pistons, rotating on a fixed spindle in which are cut the induction and eduction ports. The pistons carry gudgeon pins having slippers which work in an annular groove on the inside of a revolving drum. The gudgeon pin centres are thus constrained to follow a circular path, and if this path is so set that its centre coincides with the centre of the fixed spindle no radial motion is communicated to the pistons; but if the centre is moved to one side or the other, liquid is pumped in and out, the rate of delivery varying with the amount of eccentricity and the direction according as the path is moved to the right or the left. The revolving drum or floating guide ring, can be adjusted to any desired position, but rotates freely on ball or roller bearings which are carried on guide blocks sliding in grooves in the main casing of the pump and connected to the stroke-varying spindle.

When the cylinder body is revolved, the floating ring revolves with it, the resistance of the slippers being greater than that of the bearings. In the central position, the slippers make no movement in their grooves, and in any other position, move too and fro only to an extent directly proportional to the stroke. A great saving of power is effected in this way, and the fact that the drum revolves confers another advantage. If the slippers moved around a groove in a fixed case, that case would have to be retained full or partly full of oil for the sake of the lubrication, and the churning up of the oil would mean waste of power; but because it rotates with the cylinder body and slippers, it can be kept full of oil by centrifugal force and yet no churning occurs.

Motor Features.

The motors also present several novel features, one of these being the use of a cam which forms a track for rollers on the piston crosshead. This cam enables a large lap to be used in the valve action and reduces to a minimum the loss by slip or leakage in passing from the suction to the pressure side; it further enables the motor to work under its full load and at high speed without injurious vibration and without causing serious fluctuations on the pressure gauge, even at pressures up to 1,500 or 2,000 lbs. per square inch. In dynamometer tests, this motor has shown an efficiency exceeding 95 per cent., while in the motor truck, which is the first of its kind to be constructed and is therefore largely experimental, the overall transmission efficiency at the road wheels exceeds over 76 per cent. at eight miles an hour and 72 per cent. at 12 miles an hour, its maximum legal speed. Running at this latter speed on the level, the engine makes about 600 r.p.m., and the oil pressure is about 200 lbs. per square inch. Any lower speed can be obtained simply by reducing the stroke of the pump, and the same action serves to brake the vehicle on a decline; rapid acceleration and retardation being effected with remarkable smoothness and absence of shock.

In order to maintain speed on ascending a steep hill, the engine is accelerated and the pressure may rise to 1,200 or 1,500 lbs. per square inch; 2,000 lbs. being the limit for which the apparatus is designed. Many other applications of this system of hydraulic transmission can be suggested, such as lifts and hoists, cranes and sheer-legs, machine tools, hydraulic presses, etc.

ALTERNATING CURRENT RAILLESS TROLLEY.

ACCORDING to the Electrical Review, the first alternating current railless trolley in the world is being shown in working order on a tar macadam road, by the Gesellschaft fur Gleislose Bahen Max Schliemann and Co., at the Electrical Exhibition of Leipzig. This is an electric omnibus traveling on a strip of tar macadam 100 feet in length, which has been rolled on an existing uneven stone pavement 6 cm. in thickness, after scratching out the joints as far down as possible. The omnibus is operated by a 1000-volt single-phase commutator motor of 15 horse-power output, 1,200 revolutions per minute, 50 cycles, which is started and controlled by shifting the brushes.

The motor drives the rear axle through a double cardan shaft and a worm gear of 10 to 1, and the rear wheels by an elastic clutch. The form of current, the voltage, and the use of a repulsion motor constitute decided novelties in this connection. The rubber tires are guaranteed for 20,000 kiloms., but 40,000 kiloms. have been reached in actual operation, corresponding to a cost of 1 cent per kilom. The vehicle is lighted by metal filament lamps. The speed is 20 kiloms. per hour, the average consumption being ½ kilowatt-hour per kilom.

NEW SHUNTING LOCOMOTIVE.

A NEW shunting locomotive, recently built for the New York, New Haven and Hartford Railway, differs from those of earlier design. The difference lies in the fact that the locomotive has but one operating and controlling equipment, which is mounted in the centre of the cab. Thus, the driver always stands in the centre of the cab when running in either direction. The master controller is suspended from the roof. The locomotive was equipped in this manner in order to determine which was the better arrangement for shunting service, a double-end control—duplicate operating and controlling equipments at each end of the cab, or a centre-cab control.

Canadian Imports.—The imports of iron and steel from the United States for the fiscal year ended March 31st, 1912, totalled $36,382,725, as against $29,307,039 for the previous year. This total doesn't include machinery, agricultural implements, nor many other articles properly classified as iron and steel. The gain in imports from the United States during the last fiscal year in the above items of iron and steel was $7,075,686, or more than 27 per cent.

The Motor Truck's Relation to the Foundry Industry*

By C. R. Hoyme

The author of this paper treats his subject in an analytical manner, which is at once interesting and instructive. Without claiming that the motor truck is an all-sufficient remedy for transportation troubles of the factory, he points out where it may be advantageously employed, and quotes figures showing the approximate cost of operation, etc.

THE transportation problem of the commercial world to-day has reached a critical point. Cities are growing and increasing in population, homes are being built in the suburbs and factory sites are becoming scarce in the cities, making it necessary to take ground in outlying sections, where railroad facilities are usually non-existent. What is the answer? "Motor transportation." "That sounds well," says the business man, "but is it practical, economical and can it be relied upon?" This depends largely on the kind and quantity of business and the relation of the markets to the source of production. The value of the motor truck lies in the fact that it extends the radius of action, decreasing the time of delivery from one-half to one-third of that of the old style horse method and under absolute control of the purchaser. From the standpoint of economy it has proved to have doubled the volume of merchandise handled and to have halved the cost, displacing from two to three double teams, thus saving the wages of two drivers.

Clinton 5-ton truck carrying a 6-ton load of large cast iron pipe.

Proved General Business Utility.

For the purpose of illustration let us take the Baldwin Locomotive Works. They are to-day using four Saurer 5-ton trucks, displacing twenty-four horses and twelve wagons, at an approximate saving of 33 1-3% per year. The Commercial Car Journal, a well-known publication, recently made a canvass of motor truck users, and asked an opinion as to whether their experience with the commercial car in every day use was such as to lead them to regard it as in an experimental stage, or whether it had passed this period and was a successful, practical and economical machine. Eighty-one per cent. replied in the affirmative, which proves conclusively that the motor truck has come to stay.

Utility in the Foundry Trade.

I have shown that it meets the requirements of general business, but, may it be successfully adapted to the use of the foundry trade? Before this question can be answered, there are a number of conditions to be investigated. We must first determine the length of the hauls; second, the general condition of your transportation department; third, the amount of material handled; and fourth. your present cost of transportation. We can then decide whether motor trucks can be utilized in your particular business to an advantage.

The Midvale Steel Company, started the ball rolling by placing one 3-ton truck in the delivery department, under whose jurisdiction came the transportation of the car wheels, tool steel, billets and general castings to their down-town customers. This was previously done by hired teams, and the truck is, to-day, advantageously doing the largest part of their hauling.

The Tiega Steel Company are also using a truck of 5-ton capacity, which is operated at a much lower cost than by the old style method; besides it makes from two to three trips a day more than could ordinarily be done by the work of four horses, which proves again that the motor truck is essential to the proper, economical transportation of foundry product.

Short Haul Feature.

Motor trucks, as to-day manufactured, are required to stand the excessive strains of heavy hauling, therefore, the materials used in their make-up, especially those of the heavier type, should be the best obtainable. The necessity of having ample power to haul the load at the rated capacity of the particular truck has also been worked out from a practical and common-sense standpoint. The use of a too powerful motor in a light truck would be ultimately disastrous, for the simple reason that it would not take long for the motor and the truck proper to shake themselves to pieces.

Motor trucks are manufactured of capacities ranging from one thousand pounds to 10 tons, of both electric and gasoline power, and just here, let us say that the electric type can be utilized to an advantage in a great many instances over the gasoline type. Take for instance, the foundry hauling about 3 miles from its plant, with numerous stops. Here, an electric truck will be the more economical, as the distance covered is not particularly great and the

*Abstract of paper read recently before the Philadelphia Foundrymen's Association.

many stops naturally require time for starting and the extravagant use of fuel in the gasoline truck. This example does not necessarily indicate that electric trucks can only be used for a three-mile trip. It goes to show, however, that for some kinds of service, the electric is the logical choice.

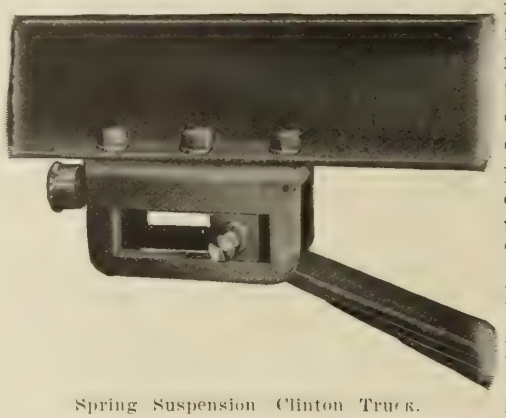
The electric is the right selection for some branches of city service by reason of the fact that the roads to be travelled over are usually passable. The better the roads, the better the performance of the car, for it must be born in mind that the electric is, in a sense, limited. Hard roads pull down the batteries, but do not have the same effect on gasoline cars, where sufficient fuel can be carried for a long run.

The Gasoline Truck.

We have considered the transportation problem from the short haul standpoint, and in taking up the question of utilization of the gasoline truck, I should say that where you have a long freight haul and where the roads are hilly, muddy and sandy, the gasoline truck is that to be selected. Before a business man buys a truck, he should first secure figures showing the average cost of hauling his material or finished product per year, then by careful investigation, determine whether his particular work calls for an electric or gasoline truck, comparing the cost of up-keep of the two latter models of transportation to that of the existing cost, and taking in consideration the increased service and the possibilities of new business. I have seen instances where business houses have installed a motor truck of 5-ton capacity where requirements call for 3 tons. This is a big mistake and a matter that the purchaser should consider seriously. The right truck in the right place, operated with a degree of care cannot fail to be economical.

Constructional Features.

The construction of a good motor truck should involve the following:—A four cylinder motor with ample power to pull the load at a speed of from ten to fifteen miles per hour over all kinds of roads; good substantial transmission with gears heavy enough to stand the strain and shocks of the average cobble stone street and rutty roads; a clutch



Spring Suspension Clinton Truck.

that can be engaged freely and gently so as not to strain the motor or transmission; the right kind of jack shaft, preferably of the full floating type; substantial frame, with enough resiliency to give yield with the condition of the road bed; large tires; heavy springs, yet resilient enough to carry the load as easily as possible; wheels, necessarily of heavy construction, and the axles both front and rear of solid composition to withstand road shocks. Motor trucks of to-day have followed this general method of construction. Each year, they will naturally improve, not only in design, but in materials to take the place of that which is now employed.

The tire problem seems to be the bugaboo in economical up-keep, but there is no doubt that this will be overcome in a few years. We cannot class the motor truck as an absolutely perfect device, although its manufacture has been carried on for seventeen years abroad and about ten to fifteen years in America; yet, each and every day, something new develops to increase the efficiency of this labor-saving machine.

Cost of Up-keep.

Nothing has been said as to the general cost of up-keep of motor trucks, and it might be well to dwell upon this point to show, or to outline, the general estimated cost of operating a 3 or 5-ton truck for a period of one year on a basis of fifty miles per day. First, we must consider the initial investment. Suppose a three-ton truck for the chassis cost $3,500.00, and the body $250.00, the complete investment would be $3,750.00.

Interest on investment at 6 per cent. per annum	$225.00
Depreciation of body at 20 per cent. per year	50.00
Storage, including washing, polishing and inspection	300.00
Driver's wages at $15.00 a week	780.00
Insurance, fire, $99.00, liability, $80.00, property, $32.00, collision, $108.00, total	319.00
Depreciation of truck at 10 per cent. per year	375.00
Annual expenditure for overhauling	200.00
Total fixed charges per year	$2,249.00
Total fixed charges per day	7.50

Operating Costs.

The operating charges would be as follows:

Gasoline at 8¼c* per gallon, operating seven miles to the gallon	.0121
Oil at 30c per gallon, operating 200 miles to the gallon	.0015
Tires at approximately $470 a set, 8,000 miles guaranteed	.0587
Total cost per mile	.0723

This, on a basis of 50 miles per day would be $3.615. While these figures are approximate, they give an idea of what it costs to operate a truck of that capacity.

Trucks for economical employment in the foundry would be those of capacity from one to five tons, the cost of operating being proportionate to the capacity and investment. The average cost of a one-ton truck is $2,150; two-ton, $3,000; three-ton, $3,500; four-ton, $4,000; five-ton, $5,000. Tire companies guarantee tires on the larger trucks from 8,000 to 10,000 miles, depending largely upon the route covered, loads carried etc.

Schact 2-ton Truck, loaded with Hardware in Packing Cases. The Schact Motor Car Co. of Canada, Ltd., Hamilton, Ont.

*It is now more than double this price.—Editor.

The Truck Operator.

The question of the operator should be very seriously considered, as the general cost of up-keep, length of service, depreciation and tire expense largely depend upon him. Experience has shown that it is a great deal cheaper to put on a man of some mechanical ability and to pay him about from $15.00 to $18.00 a week, than to get a cheap man for $9.00 a week who knows absolutely nothing about machinery. The latter man will be a ceaseless worry to the owner, oftentimes operating the truck without the proper lubrication, careful general supervision and inspection that a piece of machinery doing this kind of work must have. Would the business man ordinarily put a $5,000 investment in the hands of a $9.00 man to handle for him? When you stop to look at it from this viewpoint, it only goes to show that high wages spell economy in the end. The motor truck must have a certain amount of attention. It requires rest like a human being, and the truck that is operated day in and day out without attention will soon end up in the junk heap.

Truck Body Construction.

Another important matter in connection with the adoption of the motor truck to the necessities of the foundry is the construction of the body. Experience shows that a substantial platform lined with sheet steel, built as close to the ground as possible, has proven to be the most satisfactory. There is a tendency when loading the truck with heavy castings, to block them; and nailing them to the body floor soon cracks it and puts it out of commission. By the use of the steel covering, loading is much more quickly accomplished, and it is very much easier to move a heavy casting over a smooth surface.

One of the most useful accessories that can be applied to commercial cars for such work as loading of heavy machinery and castings, is the power winch. The cost of a power winch is considered a little high, but the disregard of power winch efficiency from the standpoint of increased cost of the equipment alone is very short sighted. The power winch can be used in any sort of service where loads are bulky and heavy, the shifting of which would consume time and mean strenuous human effort. The winch can be operated by turning a crank, or direct from the motor, for both hoisting and lowering.

The Schact Truck.

Numbers of Canadian concerns are now turning out high grade motor trucks suitable for every class of transportation. Prominent amongst these is the Schact Motor Car Co., of Canada, Ltd., who have a well-equipped factory at Hamilton, Ont. The "Schact" trucks have been designed for heavy duty service, and being considerably under-rated in capacity they will readily take 25 per cent. overload without any appreciable strain on the motor or working parts. These trucks are built in sizes of 1-ton, 2-ton, 3-ton, 4-ton, and 6-ton nominal capacity. The four cylinders are cast en bloc, the valves being on the right-hand side and completely enclosed. "Mea" magneto ignition and "Stromberg" carburettor are fitted; consequently engine and ignition troubles have been successfully eliminated. Unless otherwise specified, a left hand drive is fitted, and, in addition, these trucks are now being built with centre control, a feature which the Schact Motor Car Co., were among the first to adopt. The Hamilton plant, which has now been in operation about a year, has met with encouraging success. Mr. F. L. Reid was recently appointed general manager; he having previously held a similar position for two years with the parent company in Cincinnati.

Six ton Knox-Ajax truck with box body. Canada Foundry Co., Ltd., Toronto.

The Clinton Truck.

Another prominent Canadian truck is the "Clinton," made by the Clinton Motor Car Co., Ltd., Clinton, Ont. This truck is fitted with what is known as the Unit System Power Plant. The motor, clutch and transmission are all housed in an aluminum case. This is supported by one trunnion in the front, attached to the front cross member of the truck, and by two trunnions at the rear, resting on bearing secured to the side members. The engine is fitted with a self starter. An interesting feature of the Clinton truck is the spring suspension, illustrated on page 236. The end of the spring is attached to a square block, which slides in a grooved frame of manganese bronze. Patents in Canada and the U. S. A. are pending on this device which is an exclusive feature of the Clinton truck. This arrangement of spring suspension displaces the system of shackles and rollers used on some cars. It ensures smooth running over very uneven surfaces and eliminates sudden jarring. The Clinton truck is built in 1-ton, 2-ton, and 3-ton sizes, while designs for a 5-ton truck are all complete. The latter size is built to order.

The Canada Foundry Co. Truck.

The Canada Foundry Co., Ltd., Toronto, Ont., are about to take up the building of motor trucks. Before deciding to do so they went into the matter very thoroughly in order to satisy themselves as to the saving which might be expected by their use. With this end in view, the company built three trucks of 1½-ton, 3 tons and 5 tons capacity for use in their own business. They next proceeded to carry out a series of careful tests between horses and trucks, and as a result, it was found that for the same number of ton-miles, the 5-ton truck effected a net saving of about $18 a day over horses. This extremely satisfactory figure determined the company to take up the building of motor trucks and they at once sent representatives on a tour of inspection with a view to picking out a suitable model. Finally, an agreement was reached with the Knox Automobile Co., Springfield, Mass., by which the Canada Foundry Co. were given building rights. This truck will be known in Canada as the "Ajax."

The Knox motor has several interesting features, not the least of which is the water circulation. A centrifugal pump is driven by helical gears from the cam shaft through a flat safety spring coupling. The driving is done by this flat spring engaging two lugs on a disk fixed to the end of the pump spindle. The spring is, of course, stiff enough to take the drive under normal conditions; but

if the pump freezes or becomes clogged, the spring will snap by the lugs and, thus, any damage to the pump blades, shaft or gears will be avoided. The engine is fitted with a governor which can be set to any predetermined speed and then locked and sealed, thus preventing the operator from exceeding the speed set by his employer. Ignition troubles are eliminated by having a dual system, providing two sparking plugs in each cylinder and two methods of supplying current to either set, viz: dry battery and "Bosch" high tension magneto.

The Canada Foundry Co. expect to commence building these trucks before the end of this summer and will organize a department entirely devoted to this class of work.

ELECTRIC LOCOMOTIVES.

EXPERIENCE with electric working on the New York, New Haven, and Hartford Railroad has now resulted in no less than seven kinds of locomotives being built. The original type was evolved to meet the troublesome conditions of the company's service into New York, where both alternating and direct currents are employed. For combined freight and passenger service there is a second type of locomotive, consisting of two sections, each having two driven axles in a rigid wheel base and a pony truck. This is used for single-phase operation in the Hoosac tunnel. There are also two experimental types, one modified from the second type and the other equipped with side rods. Still another type is a group of switching locomotives solely for alternating current, while another type is intended for combined freight and heavy passenger service. Finally, there is the new Colonial type designed particularly for fast, heavy passenger service.

In all, the company now possess 82 locomotives of these seven types. The Colonial locomotives are particularly interesting on account of the use of three separate wheel bases, consisting of two four-wheel radial trucks and two pairs of rigid drivers in the centre. Each radial truck has a pair of driving wheels and a pair of small pilot ones. Each pair of drivers is provided with two motors permanently connected in series, and having pinions geared to the same axle sleeve, by which several advantages in operation are obtained, including light construction and economy in the space required for the mechanism.

ENGINEERING CLASSES IN WINNIPEG.

THE annual short courses in steam and gasoline engineering, which are being held for the fifth time, closed on June 28. The total number in attendance was sixty-two, most of whom are residents of Manitoba, while not a few have come all the way from Saskatchewan, and the class included men of all ages from 17 to 45. Thirty students received instruction in steam engineering under the direction of Professor L. J. Smith, B.S., assisted by R. Milne, B.S.A., and thirty took the gasoline engine course, under W. J. Gilmore, B.S., who is assisted by Russell Rice. These courses are carefully planned with the object of aiding, not only those who have already acquired some knowledge of steam or gasoline engines, but also those who have had no previous experience in their operation, and who realize that such knowledge is essential to success in modern farm management. The large engineering building at the Agricultural College is well equipped for the teaching of a practical course of this kind. It contains steam and gasoline engines, testing apparatus, valve models, and other appliances necessary for demonstration work.

In addition to the engines already at the College, arrangements have been made with the large tractor firms to have at least ten different tractors sent up for use during the latter part of the course, so that the students will have an opportunity of handling and becoming familiar with the various types of engines on the market.

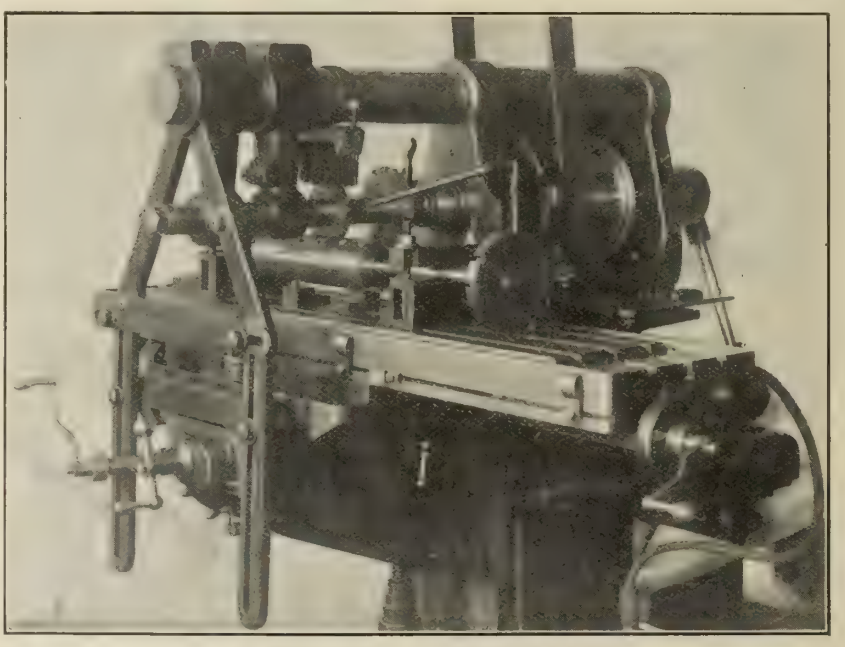
A GOOD MILLING PERFORMANCE.

IN the headquarter shops of the Canada Machinery Corporation, Ltd., at Galt, Ont., no means are neglected by which production may be increased without departing from a high standard of workmanship. While the example of milling practice described and illustrated is but one of the many high speed performances to be seen there, it is nevertheless not the least interesting.

As shown, the work to be milled is a safety cylinder, or cutter head, for a wood working machine. It is made of .60 carbon steel, and the particular requirement is that of cutting slots 1½ inch deep by 1 inch wide. Each slot is cut at one operation, the feed being 4 inches per minute. The 6-inch diameter by 1 inch face cutter runs at 50 R.P.M., and has inserted teeth of "Saben Extra" high speed steel. The lubricant used is Mystic compound under pressure. The wire brush seen in contact with the cutter prevents the latter being jammed sideways by the cuttings. The larger milling cutter seen behind the work has nothing to do with the job in question. It will be generally agreed that the accomplishment of the task constitutes a very excellent performance, and speaks well not only for the cutter, but also for the milling machine. The latter is a No. 4 Cincinnati, and is by no means new, having seen a good many years of useful service.

Other good performances carried out in this shop are: (1)—Machining iron castings on a vertical boring mill at a cutting speed of 225 feet per minute, with ¼ inch cut and 1-16 inch feed. (2)—Turning a .35 carbon steel shaft, 9 inches diameter by 10 feet long, at 110 feet per minute, with ¼ inch cut and ⅛ inch feed. "Saben Extra" is used in both cases, the turning tool in the second example being ¾ x 1½ inches.

We are indebted to Mr. R. Power, general superintendent, for the above particulars and for the photograph from which our illustration is made.



A GOOD MILLING PERFORMANCE.

RAILWAY SIGNALLING EXPERIMENTS.

INTERESTING experiments have recently been made near Birmingham, England, with a remarkable invention designed by Mr. H. von Kramer, with the object of preventing train collisons. The inventor's method is to have earth-buried wires laid alongside and parallel with each line of permanent way, which will communicate with the signal boxes all along the line. The guard's coach on the train is fitted with a coil framework, whence electricity emanates, connecting with the buried wire. The signal is picked up from either the wire or the train by a "detector," and automatically magnified, so that it is capable of operating a bell, hooter, or even a brake. In the guard's van are several electric "solenoids," erected on a marble slab, which are entirely automatic. When the detector operates, one of these rings a hooter, while another is used for pulling a lever in the van which puts on the brakes and stops the train. On the other hand, the train can signal from station to station, sending out a current which operates alarm bell and lamps.

If the signalman forgets to pull back a lever after a train has passed from one block section into another, this omission is automatically rectified by the current. If the train overruns a signal at danger it will be automatically stopped, and will not be able to proceed until a seal has been broken in the signal box, where the incident is recorded. This automatic signal will not be blindly relied upon by the engine driver and signalman, but rather increase their alertness, as they are certain of having their mistakes recorded without question of doubt. There is a recording instrument in each box which, when straight, indicates that all is right, but if any trouble occurs it goes up at the exact moment of the incident, and remains in a position of danger.

An outstanding feature of the invention is the extreme delicacy of the detector, which can be tuned to any pitch and only respond to a similarly tuned instrument. For instance, one tuned to 100 frequencies (vibrations) per second would not respond to others of even 95 or 105 frequencies. Moreover, the detector is tuneable to such an extent that the signalman can distinguish between goods, slow passenger, and fast trains. It is impossible for two trains to collide in the same section. If one gets in legitimately it is all right, but if a second runs over the block, both trains are automatically stopped. The experiments are being carried on over a ten-mile stretch of the Stratford and Midland Junction railway betwen Stratford and Kineton, and so far have proved a striking success.

RAILROADS USING OIL.

THE consumption of fuel oil in the United States is steadily increasing, according to a report by David T. Day, of the United States Geological Survey, on the production of petroleum in 1910.

During that year, the quantity of fuel oil consumed amounted to 24,586,108 barrels, as compared with 19,939,394 barrels in 1909, an increase of 23.3 per cent. In the vicinity of oil fields or where cheap water transportation can be secured, as along the Pacific coast, the cost of operating with oil is less than with coal. The use of oil, as a source of motive power for railroads, offers, aside from the use of electricity, the only certain guarantee of immunity from the hitherto generally prevalent fires along railroad rights of way. The adoption of oil as fuel on the C.M. and St. P. lines west of Butte and on the Great Northern west of Lavenworth, with a proposed extension eastward to Spokane this summer, gives great encouragement for the adoption of similar measures by the railroads of Canada on portions of their lines.

Already, the Canadian Pacific Railway announces the establishment of oil-burners, effective July 1, on that portion of its line in British Columbia between Kamloops and Field. The Esquimault and Nanaimo railway, running northward from Victoria on Vancouver Island is equipped with oil burning locomotives. The economy in the use of oil along the Pacific coast is further shown by its adoption, in place of coal, on the Canadian Pacific Railway and Grand Trunk Pacific steamers. No one thing would go so far to prevent continued destruction of the magnificent forests of British Columbia as the use of oil on locomotives running through forested portions of that Province. The hardship upon the railroad companies would not be material, and, in comparison with the tremendous public interest at stake, would be infinitesimal.

ELECTRIC HEATING.

CHEAP hydro-electric power generated on the Snake River has caused the rapid development of the city of Twin Falls, Idaho, and has rendered practicable the electric heating of buildings. In the vicinity of Twin Falls electric heating units to the extent of almost 1,000 k.w connected load have been installed in place of steam radiators. A six-room house uses $70 to $100 worth of electrical energy during the season of eight months, and a building having stores and offices on the first floor and a ball room on the second story uses 100 k.w. at a cost of $625 for the season. Three-phase current is brought into the latter building at 2,300 volts, and is transformed to 220 volts for use in 40 electric radiators and a water tank heater, which keeps the water continually at the boiling point through thermostatic control. The size of the building is 50 feet by 120 feet, and the electrical equipment, exclusive of the transformers, which were supplied by the power company, cost approximately $1,000.

ECONOMICAL WORKING OF STEAM BOILERS.

A DEVICE for the consumption of smoke in boiler furnaces and for economizing the heat, installed in a silk mills in Matteawan, N. Y., by the Furnace Gas Consumer Company of Newburgh, N. Y., consists of a number of tubes made of refractory clay, which are placed end to end in the furnace behind the bridge wall in such a manner that the draught from the fire passes through them. When the fire is incandescent, the tubes are stated to absorb a large amount of heat, which is given out when fresh fuel is charged into the furnace, so that the gases therefrom are completely consumed. During tests with a 100 h.p. boiler, the heat from the tubes and from the asbestos packing between them and the boiler sufficed to generate sufficient steam to enable the boiler to be worked at full load for 12 min., while with a banked fire overnight, the pressure available in the morning has been more than double that which has been obtainable under ordinary conditions.

STAY BOLT THREADS.

ACCORDING to inquiries made by the "**American Machinist**" among locomotive builders, it is found that in nearly all cases stay-bolts for locomotive boilers are being made with the Whitworth thread. This is done for two reasons:— Specifications for locomotives for foreign countries always mentioned Whitworth threads, and boiler makers fell into the habit of making their taps and dies with rounded points, so that they were practically getting Whitworth conditions. Even with the United States standard thread the stay-bolt tap is very apt to become rounded on the top, as the boiler sheets are often quite hard.

Fraser and Chalmers, Ltd., 4 Phillips Place, Montreal, have been appointed agents for the Terry Steam Turbine Co., Hartford, Conn., in Eastern Canada, which includes Quebec and the Maritime Provinces.

STANDARD PARTS FOR PILLAR DIES.

By L. E. Gehman.

THE writer of this article realizes that every manufacturer who has a punch press department in his plant is trying to standardize his punch and die parts so that they can be manufactured at less cost and placed in the machine in as short a time as possible.

While employed on the mechanical staff of a large typewriter manufacturing company in the States, I was called upon by the management to standardize all punch and die parts as well as subpresses, so that any punch and die could be used in any press that was heavy enough for the operation. Believing, therefore, that the readers of Canadian Machinery are always interested in the most modern developments, the writer feels sure that a complete description of the punch and die practice of this company will appeal to them, as there is embodied many novel and interesting features.

Sub-Press Castings for Blanking Dies.

Fig. 1 shows the design of sub-press base and plunger castings for blanking dies, and the tabulated list following shows the dimensions of the four stock sizes, which are of correct proportion, and might be used in other shops. This, however, is a larger variety than necessary for most shops. It was found necessary to provide this range of sizes for handling all the blanks produced, which ranged within wide limits.

All punches and dies are of the pillar sub-press type, as time saved setting-up, and the fact that there is no danger of the punch and die getting out of alignment, more than make up for the added cost over the common open style punch and die. The base casting is secured to the bolster on the press by plain bolts; slots being provided for this purpose. Plain guide pins are used, one being made smaller than the other to avoid the possibility of putting the punch and die together incorrectly. The plain guide pins are cheaper than those provided with oil grooves, and are more rigid than those set into bushings in the base. The plunger is secured to the ram of the press by a novel method; a description of which is really the most interesting part of this article, and the most important point in the standardization of the punches and dies in this particular shop. A V-slot is provided, made to gauge to fit a V-block on the adapter, which is applied to every press in the shop. By this means it is possible to use any punch and die on any press in the plant. This fact is of the utmost importance, as usually when designing a punch and die it is necessary to designate the presss on which it is to be used, and make the punch and die to fit same.

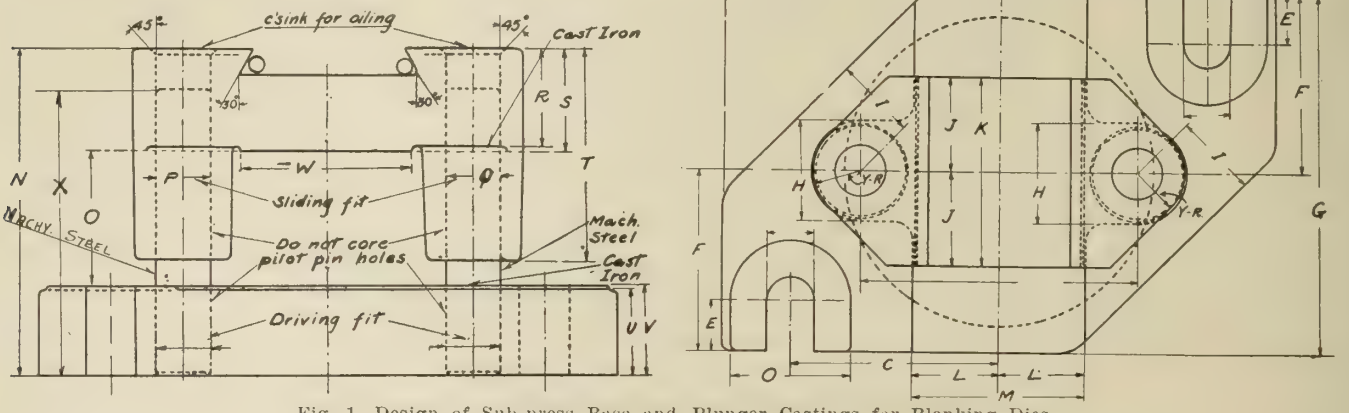


Fig. 1—Design of Sub-press Base and Plunger Castings for Blanking Dies.

Styles of Adapters.

Fig. 2 shows two styles of adapters. These adapters were made in several different styles to fit different presses. It will be seen that they consist of a V-block (A) fitting the slot in the top of the plunger, which is secured to the body (B) by threaded portion of part (C). Thus, it can be seen that the V-block may be swung to any angle without loosening the screws which secure the adapter to the ram, or removing the adapter. As every press in the shop is equipped with one of these adapters, they are considered part of the press, and are not ordinarily removed from it.

Before the adapters were attached to the presses they were all made to have the same working clearance between the end of the ram when down and the bed of the press. This was done by finding the press which has the least amount of room under the ram, with the adjustment about two-thirds of the way up. In the smallest press this was found to be 5⅛ inches, using a one-inch bolster. All the other presses were brought to this figure by using suitable adapters and thicker bolsters; thus, the result was obtained of being able to use any punch and die made in any press, provided only that the press was heavy enough to handle the work.

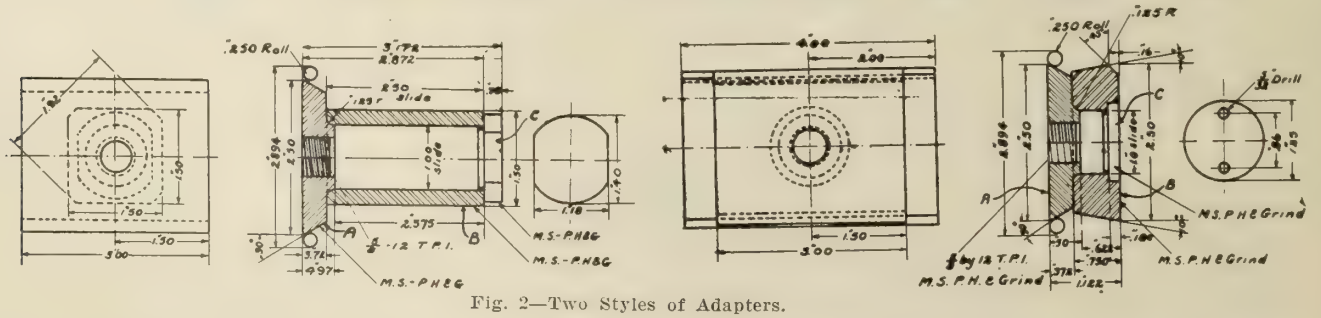

Fig. 2—Two Styles of Adapters.

Castings for Bending Dies.

Fig 3 shows the style of base and plunger castings adopted for bending dies, made in two sizes (see tabulated list). These are of open construction, having both the guide pins in the back. A punch and die fitted to one of these sets of castings is easy to load, the front being entirely open. This style is, there-

fore, far superior to those with guide pins on the sides for bending purposes.

Blanking Punch and Die.

Referring to Fig. 4, there is shown a sample blanking punch and dies made in this shop, which embodies many desirable features, being of economical and efficient design and standardized in more ways than one. The stock handled in this particular punch and die is .041 inch thick, cold rolled soft steel. The die consists of a piece (15) of Brown and Sharpe ground stock ¼ inch thick, hardened and set into a block of machine steel (13), and secured to the base casting by screws (20) and dowels (19). The tool steel block is fastened to the machine steel block by screws and dowels (30 and 28). In the No. 1 and 2 presses, the parts (15 and 13) are of standard thickness, ¼ and ½ inch respectively, but the length and width are optional, depending on the job in hand.

Tabulated List Showing 4 Stock Sizes for Blanking Die Castings.

The B & S ground stock comes in regular widths and thicknesses, ready ground to size, and no further machine work is required to fit the die made from this material to the machine steel block. The economy of this construction is easily seen. With the inserted ¼ inch plates, stock 3-32 inch thick can be satisfactorily blanked, and has been used for ⅛ inch stock. When the stock is unusually thick for a small blank, a solid tool steel block is used. With the No. 3 and 4 presses, ⅜ inch inserted plates are used on account of the blanks being generally thicker, as they are larger. The stop (29) is made of machine steel and pack hardened. It is not made standard as to size, but to suit the particular job on hand, and is generally in shape a straight piece, but on account of its position, the blank, in relation with the strip of stock in the die shown here, is provided with a projecting end for clearing the hole in the stripper. The stop swings on a pin (27) of hardened drill rod, screwed into the stripper plate, and is also provided with an adjusting screw (25) and check nut (24), by which any slight adjustment may be made, rendering unnecessary the use of extreme accuracy in locating the stop in the first place. The extreme simplicity of this form of stop makes it cost probably about one quarter as much to make as the stops in general use. Of the guide

Fig. 5—Bill of Material for Sample Blanking Punch and Dies.

strips (16, 17 and 18), one (17) is moveable on pins (22), being provided with a flat spring (21), so that it presses the stock firmly against the front guide strip (16). These are made of machine steel and case hardened. The stripper plate (12), of machine steel, is of standard thickness, 3/8 inch, and of size to suit the die.

Referring to the blanking punch (9), it will be seen that it, as well as the piercing punches, are headed over and held under in a 1/2 inch machine steel plate (8) with a 1/8 inch pack hardened plate (7) behind it. This is an excellent construction, and it will be noticed that the piercing punches are only formed for a short length to the diameter they are to pierce; being made of considerably larger stock for added strength. The pilot shown here is made solid instead of having a spring behind it, this being in most cases considered a superior construction. This point is, however, open to question.

The action pin for the stop is simply a 1/4 inch filister head screw, screwed into the plunger casting, and having a check nut for adjustment. Plate 3 is screwed to the front of the plunger casting, with the part number and name of the piece to be made in the punch and die.

The use of a bill of material for parts not detailed is a good idea, but the one shown for Fig. 4 is an improved style, as all parts of the punch and die are called for here, whether detailed or not, so that the foreman of the toolroom can write his material orders from it, without the possibility of missing any of the parts. Reference figures are placed down the middle of the sheet in a straight row, making it easy to identify any particular piece.

As all the parts are called for in the bill of material, it is necessary to detail but three as shown; other figures where necessary being placed directly on the assembly drawing. As the most of the parts are square or regular shapes, the dimensions given on the bill of material are sufficient. The foregoing examples show modern and approved practice.

INDUSTRIAL ACCIDENTS.

ACCORDING to the industrial accident record of the Department of Labor, 62 persons were killed and 249 injured during the month of June in the course of their employment. A comparison with the records of the previous month and of June, 1911, shows that there were 28 fewer fatalities than in May, and 30 less than in June, 1911. Of the non-fatal accidents, there were 8 more recorded than in May, and 137 more than in June, 1911. There were but 2 accidents recorded involving the death of more than one workman. One occurred on June 1, by which 8 construction laborers were killed during blasting operations on railway construction work near Stones' Corners, Ont., and the other a head-on collision of railway trains near Nipigon, Ont., in which 4 railway employes were killed.

U.S. FOUNDRY AND MACHINE SHOP CENSUS.

ACCORDING to statistics recently published by the United States Census Bureau, there were 13,253 foundry and machine shop establishments in the United States, employing 615,486 persons, when the last census was taken. Of the total 9,851 were proprietors and members of firms, 21,754 were salaried officers, superintendents and managers, and 52,869 were men and women clerks. The average number of wage earners was 531,011. The value of products was $1,228,475,148, and the value added by manufacturing processes or the difference between the value of the finished products and the cost of the raw materials, was $688,464,000. Pennsylvania took the first place with an average of 86,821 wage-earners, $210,746,257 value of products, and $109,735,517 value added by manufacture. New York held the second place with $154,370,364 value of products and $92,749,146 value added by manufacture, but it was third in regard to its average of 64,066 wage earners.

Castings for Bending Dies.

PREVENTING SHORT-PAID POSTAGE.

THE Daily Consular and Trade Report contains the following letter, which shows how one firm has endeavored to master the situation, regarding short-paid postage.

"All stenographers are trained from the time they begin work at our place to use for domestic mail, United States light-colored stamped envelopes. All letters addressed to foreign countries must have a blue envelope without a postage stamp on it. Every evening the clerk who has charge of attaching stamps takes the letters in blue envelopes and after first selecting those that go to foreign countries where two cents is sufficient, such as Mexico, Canada, Cuba, Great Britain and Germany, he affixes five cent stamps to all other blue envelopes." Canadian and American manufacturers should try and escape by some such means as suggested the many criticisms made by foreigners that letters are received short of postage, especially when the penalty of such short postage is often three or four times greater than what the postage would otherwise be.

LARGEST LOCOMOTIVE IN THE WORLD.

WHAT will be the largest and most powerful locomotives yet constructed are now nearing completion in the shops of the American Locomotive Co. The locomotives are intended for use on the Virginian Railroad and are of the Mallet compound type. Each engine will weigh in working order, 540,000 pounds with 479,200 pounds on drivers. The combined weight of the engine and tender will be 752,000 pounds. The total length of the engine overall is 65 ft. 11¼ in. and the total length of wheel base is 57 ft. 4 in. These engines will have a tractive power of 115,000 pounds, or 60 per cent. more than the pioneer of this type built in America for the Baltimore & Ohio Railroad. The American Locomotive Co. system of compounding enables the tractive power at slow speeds to be further increased to 138,000 pounds when working the engine simple.

MALLET TYPE LOCOMOTIVES.

ACCORDING to the Railway Gazette there are at present something like 500 locomotives of the Mallet type in service on the different railways in the United States, Canada and Mexico.

These include practically all possible wheel arrangements and boiler designs, and, speaking in a general sense, they are working under similar conditions. While it is impossible to obtain in any considerable number of cases, the cost in money of both the Mallets and the types they have replaced, it is yet possible to glean facts concerning the majority of the locomotives in service, which permit fair conclusions being drawn as to the relative value of different types.

Mallet locomotives have in very many cases taken the place of 2-8-0 engines, and the investigation has proved that the former haul from 21 per cent, to 92 per cent. greater loads than the latter, and, in fact, that two of them will do the work for which three "Consolidations" are ordinarily needed. It is nearly on this ratio that the number of engines has been reduced on some lines. The mere reduction in the number of trains on the road, even though they be longer and heavier, introduces a very large saving from every standpoint, and one which it is difficult to estimate accurately. There is, of course, the reduction in wages of engine and train crews, and as regards fuel consumption the Mallets show an average saving of 3 lb. per 100 ton-miles.

NATIONAL POWER HOUSES.

PRESENT-day practice does not represent a final solution of the electricity supply problem. The multiplicity of power houses with their respective staffs is not economical, and the abilities of engineers at present engaged in running comparatively small generating stations would find full play in other directions if a bulk supply were available at a price low enough to secure its exclusive use in all domestic and industrial operations. The complete realization of such an object would be possible only by erecting upon the coal fields of the country, electric generating stations on a much bigger scale than anything yet attempted. From an economic point of view no question was more important in this or any country than the efficient use of coal, and no economy was so far-reaching in its effects as that of fuel, which constituted the vital force of almost every branch of industry. A gigantic scheme of this character called for the active co-operation of the Government with the existing supply authorities, and there were few home problems that could be more profitably dealt with by the legislature, or that would confer greater benefits upon the nation.

National power houses, built on the coalfields and on other sites to which coal could be cheaply transported by water, would supply the power for all extensions in existing areas, and would gradually assume the whole of the supply, as the plants in local works became worn out or obsolete. Such power houses would be equipped with high-pressure steam turbo-generators of, say, 25,000 and 50,000 kw. sizes. They would be inter-connected and distribution effected at, say, 100,000 volts to sub-stations. Transmission at this pressure was already successfully accomplished in Colorado under the most severe conditions.

The Question of Steam Generation.

It was the generation of steam that called for a radical change in present-day practice. Engineers had too long been content to use boiler plants, furnishing on an average of from 2lb. to to 3lb. of steam an hour per square foot of heating surface. Such practice involved the use of enormous boiler installations, out of all proportion to the size of the generating plants, and reference to the layouts of modern works, equipped with from 10,000 to 20,000 kw. units of power, showed a separate boiler house for each generating plant. These boiler houses were built end-on to the power house, and imposed a heavy capital cost for boilers, buildings, flues, and chimneys. They also involved heavy losses in boiler, steam pipe, and flue radiation.

THE ADVERTISING SECTION

The advertising pages of a trade journal introduce to its subscribers, purchaser and operator, the manufacturer whose product has been designed and developed to further their mutual interests. An intelligent perusal of the advertisements appearing in each issue of this journal enables definite comparisons being made between individual units of already-installed equipment and those recently placed on the market, for which more or less warranted claim is made regarding improved quality and quantity output.

The solution of these difficulties appeared to lie in the introduction of gas firing by means of flameless surface combustion on the lines first discovered by Sir Humphrey Davy, and more recently developed and described by Professor Bone. So far as investigations have gone at present, it was shown that an evaporative duty from boilers exceeding 20 lb. of steam per square foot of heating surface could be obtained easily with a thermal efficiency corresponding to the transmission to the water in the boiler of nearly 95 per cent. of the energy represented by the net calorific value of gas. At a slightly lower efficiency the evaporation might be increased from 20 lbs. of steam to 30 lbs. of steam per square foot. On these high duties the internal boiler surfaces were stated to be self-cleaning, and the scale in thin flakes became detached and was deposited in the bottom of the boiler. The boiler installation would be comparatively small and the steam range short, as all the auxiliaries would be driven by internal combustion engines.

The Supply of Low-Pressure Steam.

Many of the largest industries in the country—probably the cotton, woollen, dyeing, chemical, distilling, and brewing trades used immense quantities of low pressure steam in their various manufacturing processes. Steam for such industries could be supplied from the national power houses at less cost than it could be produced by the manufacturers themselves. Irrespective of the large economies and advantages effected by a distribution of power on national lines, such a market for low pressure steam would have a startling effect upon the economy of electrical production, as it would at once eliminate the enormous losses involved in condensers. Just as the Niagara and other large hydro-electric schemes, by reason of cheap power, attracted and promoted industries in their immediate vicinity, so national electric power houses, able to supply vast quantities of low-pressure steam at cheap rates, would attract and promote in their immediate vicinity those industries wherein steam formed one of the chief items in the manufacturing process. It was remarkable that business in this direction had not already been developed by power stations operating in the textile districts. In many areas it would be much better to invest capital in thus selling the condenser losses than in the erection of costly cooling towers and condensing plants.

There were many district steam-heating schemes in operation in America, and in numbers of instances the revenue from the heat distribution was larger than that from the sale of electric power. One of the most convincing proofs of the value of a low-pressure steam-heating business was furnished in the case of Lockport, New York, where approximately 300 buildings were supplied with heat during the colder months of the year. The company purchased electricity in bulk from Niagara Falls at one quarter of a cent per kw. hour; nevertheless, in the cold season, with coal costing $3.18 per ton (English ton), it paid the company to operate their own local steam generating plant and to sell the exhaust steam in the city.

From the heating business alone, during the cold season of about 5,400 hours, they derived an income approximately $46,875.

The foregoing is an abstract from the presidential address delivered recently before the Incorporated Municipal Association, at Leeds, England.

PROFIT SHARING IN BRITAIN.

IN the abstract of labor statistics for the United Kingdom, recently issued by the Board of Trade, particulars are given of the history of the profit-sharing system. It appears that up to June 30th, 1911, a total of 232 schemes had been started by firms, but at that date only 76 were known to be still in operation. In the four years 1889-92 as many as 84 schemes were inaugurated, only 16 of which have survived. Later experiments seem to have proved more successful; the whole of the 16 begun in 1908 and 11 of the 13 launched in 1909 being still in existence. Of the 153 schemes dropped, 40 were abandoned owing to dissatisfaction of employers with the results; 21 on account of losses or want of success; 21 because of liquidation or dissolution; 17 on account of changes in or transfer of business, and 10 owing to the apathy of the workpeople.

NEW GALVANIZING PROCESSES.

PROBABLY none of the three galvanizing processes which are in use today will be supplanted, as each, according to an article in "Stahl und Eisen," has its special advantages. The old process of dipping the articles in a hot bath of molten zinc now gives better results by the introduction of brick baths without iron lining and an increase in the quantity of surplus metal used. The electrolytic process has also been improved by the use of a more reliable and lasting electrolyte and the employment of a current of greater density to produce a deposit with a brilliant surface.

Good results have also been attained by the dry process, or Sherardisation. In this process the previously pickled articles are heated, without access of air, in zinc dust, at a temperature of from 150 cent. to 200 degrees below the melting point of zinc. An improved method, introduced by F. W. Gauntlett, consists in replacing about 80 or 90 per cent. of the pure zinc dust with quartz sand, by which balling, foliation, and accidental combustion of the zinc is avoided. The process is carried on in a revolving cylinder. An iron-zinc alloy is first formed on the surface, on which afterwards a coating of pure zinc adheres. Iron, coated by this method, may be rolled and drawn or polished without the coating breaking off.

CANADIAN AGRICULTURAL IMPLEMENTS FOR RUSSIA.

ACCORDING to the official Commercial Gazette of St. Petersburg of January last, Russia consumes approximately some $46,350,000 worth of agricultural machinery. Of this amount, the imports from abroad are valued at $20.600,000, of which the United States supplied $6,849,500, chiefly reaping machinery. Owing to the inadequate production of reaping machinery at home, Russia cannot as yet dispense with the foreign supply. As a result of the action of the United States in terminating the Russo-American Treaty of Commerce, at the end of the present year, the Russian Board of Agriculture now proposes to direct its attention to other countries as a source of supply of agricultural implements and machinery. To this end, the Board proposes to authorize the agent of the Russian Board of Agriculture in the United States to personally investigate the condition of production of agricultural implements and machinery in the big works of Canada and to purchase types of same for trial in Russia.

NOTICE TO SUBSCRIBERS.

C. Edgar, has been making collections in the Western Provinces for some of our trade and technical papers and magazines but has not made any remittance to us. Subscribers are, therefore, requested not to make payment to him and if he attempts to make collection, we would appreciate being advised promptly by telegraph, at our expense, so that we get in touch with him at once.—Maclean Publishing Co., Ltd.

FACTORY ILLUMINATION.

A SPECIAL report on illumination in factories states that as regards artificial illumination there seems to be little to choose between lighting by electric glow lamps and by modern systems of incandescent gas. Electric light has the advantage of being constant and requiring little attention beyond the systematic dusting and renewal of lamps. The gas systems generally produce a whiter and more powerful light than electric current, but the units are apt to vary much in efficiency, owing to the liability of the mantle to deteriorate. Careful attention, therefore, is required to replace any that show signs of weakness. Electric light, of course, causes no vitiation of the atmosphere; but in the modern systems of gas lighting the amount of gas burnt is so small and the combustion so complete that the effect on the air is minimized. For the perfect local lighting of any point of work the three following conditions must be fulfilled:—(1) The illumination must be adequate; (2) "glare" effects must be absent; and (3) no troublesome shadows must be cast on the work.

NOVA SCOTIA STEEL & COAL CO.

THE June output of the Nova Scotia Steel & Coal Co., was the largest this year for coal, pig iron and steel ingots. The amount of coal was 71,900 tons, that of pig iron 7,074 tons, and that of steel ingots 7,450 tons. The new hydraulic fluid compression plant at Sydney Mines was started on July 1, and proved remarkably efficient, four fluid ingots being simultaneously produced by the application of 1,250 tons pressure. The plant worked perfectly.

SINGLE-PHASE MOTORS AND CONTROL SYSTEMS.

THERE have recently been numerous improvements in single-phase motors and control systems as used on American railways. The most recent single-phase installation is the New York, Westchester and Boston Railway. The car motors on this line are cooled by air supplied by an external fan, resulting in a continuous rating of over 75 per cent. of the nominal or one-hour rating. The compensating winding is short-circuited, giving inductive compensation and making the insulation strain to earth negligible. The preventive leads are of an improved design, and the control includes but seven low-voltage unit switches, even though arranged for automatic acceleration.

During the past eighteen months, the American single-phase railways in operation and new single-phase installations have ordered car equipments aggregating 77,000 horse-power, which would correspond to the motive power on over 250 cars each equipped with four 75 horse-power motors.

The Manitoba Windmill & Pump Co., Brandon, have changed their name to that of "**Manitoba Engines, Ltd.**" The new name will more appropriately express the product of the company, as their main line of manufacture is now gasoline engines and pumps.

Vol. VIII. AUGUST, 1912 No. 8

CANADA'S WEST.

THERE appears to exist in the minds of a number of reputably intelligent people the opinion that the citizens of eastern manufacturing and older established Canada, are altogether ignorant of and asleep to the developments, achievements, requirements and outlook of their western brethren, who devote their energies to the extraction of the fruits and treasures of Mother Earth. Now and then there is borne in upon us a tale of discovery to which we prick our ears and on which we endeavor to concentrate our vision, if perchance, in pageant array, our imagination might witness the unfolded wonders and we be impressed intellectually and stirred physically to a sense of our stupendous ignorance of this land, its men, matter, and mighty improvements.

On analysis, however, and due largely to the efforts of the daily press in keeping us informed, we find much of the data furnished by the scribes who make long-interval, spasmodic dashes through a greater or lesser extent of territory, to savour somewhat of "caul kail het again." It seems to us that if the people who retail such clap-trap as "lack of perception of their duties and privileges on the part of Canadian manufacturers" would keep themselves posted daily, which can be done on the expenditure of a few cents, they would find that this new country is moving forward en masse, intimately in touch with and meeting in a reciprocal attitude the demands of its many sections and the individuals composing them.

Little fault can be found with the Canadian manufacturer, or for that matter, with his British and American brothers, on the score of alertness to and appreciation of the situation, and we may not underrate, much less slight the enterprise being shown by the East in catering to the requirements of the West. We commend, however, to the attention of our great railroad corporations, a somewhat higher sense of popular duty as the basis of their business code, a proceeding which would militate little against their stockholders' interests and contribute much to the manufacturers' distributing and therefore greater output facilities.

INDUSTRIAL TROUBLES.

LABOR troubles in varying degree of acuteness loom largely in the industrial sphere, the world over, and their cause, determined by keen observers who have studied the problem, is neither more nor less than the desire of those popularly known as the working classes toward a general betterment of their condition. It has been said that extreme poverty and, still less, grab of capital's prerogative, were conspicuous by their absence as contributing factors in the declaration of those strikes with their attendant misery, which have recently convulsed the commercial life of Great Britain and other countries, the former more particularly. The working classes have been raising their ideals upon a falling purchasing power, and the attainment of any ideal usually costs money.

There is more good than bad in the existing labor unrest, and it appears to be much easier to over-estimate the alarming nature of the movement than to overestimate the boundless possibilities of the voluntary co-operative spirit and the growth of a corporate sense. It is becoming more generally realized that industrial peace will be the outcome of an increasingly wise development of trade unions rather than of parliamentary legislation. Education, sagacity and tact are qualifications to be desired in officers and rank and file alike of labor organizations, and coincident with the degree attainment of these by the individual will peaceful achievement be recorded.

The developments taking place in every department of human thought and effort are so radical and rapid, that it is little wonder that we sometimes get out of mesh with our fellows, yet there is no reason why more attention should not be directed by employer and employe to the question of automatically adjusting themselves to each new condition as it arises. There is no lack of past experience to guide us, and to which we may turn and note that industrial enterprise is a great concentrated forward movement whose leaders in any section may not dare be tyrannous or dictatorial. We are of opinion, that never before in the history of the world has there been less contempt for and a more sincerely conscientious appreciation of the place and power of capital and labor by their respective and heretofore opposing forces than what is now merging into being as the result of more or less recent happenings. It is the privilege of Canada to benefit by the experience of older countries, and of her taking to heart the lessons and profiting thereby, we are supremely hopeful.

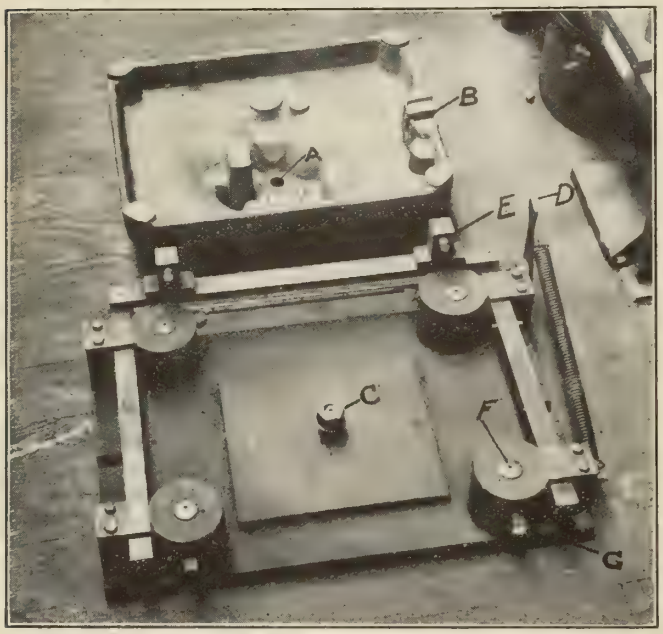
MACHINE SHOP METHODS AND DEVICES

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

SPECIAL MILLING FIXTURE.

By Avery E. Granville.

WE build a small machine which has a cast iron base, like that shown bottom side up in the accompanying half-tone. The top of this casting has a raised boss about four inches square in the centre, which is first milled off flat, and a ¾-inch hole drilled in its centre, which comes through at (A.) The bottom of the base must be milled parallel to the top of the boss, and a slot must be milled at (B) as near parallel to one side as the rough casting will permit. This is done in the fixture shown.



A Special Milling Fixture.

The nut is removed from stud (C) and the casting set over it, with the stud projecting through the hole. The nut and washer are now put on and run down with the fingers. Next, the lever (D) is released, which brings the two pins (E) against the side of the casting, lining it up. The pins (F) which have springs under them, are now released by loosening the set screws (G), and they butt up against the underside of the rough casting. The set screws are then tightened, and the pins form a solid support for the uneven surface against which they rest. Finally, the nut in the centre is given a turn with a wrench, and the work is ready to be milled at one cut, using a gang of cutters.

After the casting has been milled and removed, the set screws (G) are loosened and the pins (F) are pushed down as far as they will go, in order to make room for any possible bulges in the next casting. Then, after the casting is in place the pins are again released as described.

Very rapid work can be done with this fixture, and the work has no tendency to chatter or spring away from the cutters.

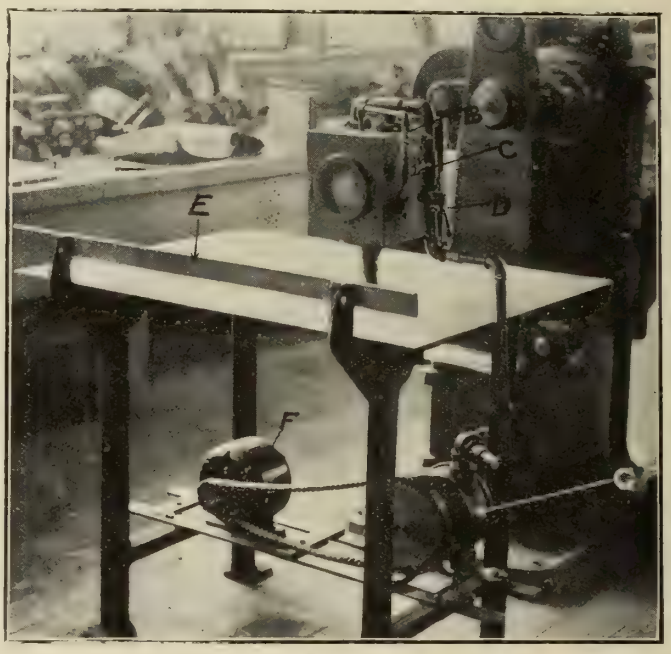
A TOOL-ROOM FURNACE.

By Avery E. Granville.

ONE of the handiest things we have in our tool-room is the small furnace shown in the accompanying half-tone. At the time the picture was taken the gasoline pipe had been disconnected to make some repairs, but when in use the pipe is connected at (A). There is a small stop-cock at (B) and a valve between the gasoline and air pipes at (C). There is also an air-cock at (D), and by using these valves as wanted, a large or small flame of intense or moderate heat may be easily obtained. The range of usefulness is almost unlimited.

We heat soldering irons by placing the points in the furnace and laying the handles on the rail (E). The ends of short rods are heated in the same way. High speed or carbon steel tools for the lathe, shaper or planer are easily heated by it for hardening, as well as other work, such as small punches or dies. Of course, this kind of furnace is not suitable for die work requiring special care. For that class of work we have a regular heating furnace made for the purpose.

The legs of the table are of cast iron with a boiler iron top bolted to them. Strips of heavy band iron support the small electric motor (F) and the pressure blower (G). This furnace saves the toolmakers a tremendous amount of time that would otherwise be spent in running to the hardening room or in pumping up a gasoline blow torch.



A Tool Room Furnace.

COMMENT ON PREVIOUS LETTERS

By Donald A. Hampson.

I NOTICE that a reader doubts if a revolving-head planer tool would work as well in practice as on paper. Some years ago, in building several special machines, there were required castings having a half round seat; some of 1 inch radius, some of 1½ inch radius and in lengths from 1½ to 2 feet. They were cast half round leaving the usual allowance for machining. Before planing, however, the circle was laid out on the ends of the castings and the inside filed down to this circle; filing at an angle of about 30 degrees with the cut to be taken, therefore, eliminating any danger of breaking out at the end of the cut, at the same time preserving the layout.

The point to be made in connection with the radius tool is that it was not used as a "stocking" tool but only as a finisher after the castings were planed down to within a shade of the filed

end with an ordinary tool. The revolving-head tool, when centered, scraped out 1-100 of an inch or so, which was well within its capacity. As a proof of the truth and smoothness of the finished work, the foreman of the machine shop at the plant having bought the lot, asked me later how those seats were "bored" out so nicely, he wanting the information for repair purposes.

Chattering.

Chattering is an effect, not a cause—the effect of insufficient support or the latter badly placed, loose parts in the lathe or of tools wrongly chosen or set. Work that is long in proportion to its diameter is notorious for chattering. On some rollers 8 ft. overall and 1 15-16 in. diameter, we used three steady rests between the ends; two might have been sufficient but as a single chatter mark meant the scrapping of the roll we deemed it wise to take every precaution. Some work needs only the slightest steadying influence and it is an old trick to hold the hand on the piece being turned. Again a piece of hardwood can be clamped on the cross slide at one side of the tool post so that its end prevents any "bouncing" of the work.

The average follow rest is of little value on slender work, for the weight of the piece sags it downward, and when starting a cut or "picking up" one, before the tool has forced the piece up into the V's, a cut deeper than the rest of the turned portion is sure to result, or if the lathe hand tries to avoid this and runs the tool out a little, a shoulder is formed that has to be filed off.

Putting in the centers without first cleaning them off and cleaning the hole out is a source of chatter. A loose headstock cap will do the same thing. Sometimes a wood wedge keeping the dog tight in the face plate slot will stop chattering, and if a lathe is old or its back gears badly worn, it is next to impossible to do a smooth job on a gear speed. In this connection, a workman could not run one of those "slim" jobs faster than the second gear speed without chatter. Another man took hold of the same job, shifted three speeds higher or to the first open speed, and the work was entirely free from marks.

A tool with a broad point ought not to be used on slender work—it cuts too much of a surface of metal and withal removes no more metal than a narrower pointed one. After a job has been chattered by such a tool it is hard to remove the tool marks. A narrow ended diamond point will generally do it, however, and the most effectual one is a tool that feeds in the opposite direction to the original broad nose, thus cutting across the furrows left by the other tool and not in them.

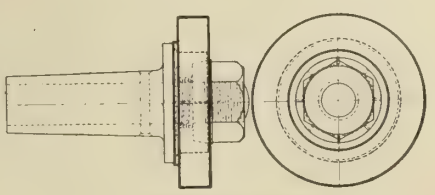
Quick Replace Work.

An instance of quick replace work is worth recounting — another will do no harm. One morning the motor driving the the main shop began to slow down. On going near to it, that unmistakeable odor was detected—the odor of a hot box. In some manner, the oil ring had jumped out of its slot and the babbitt in one box was ruined. It had melted, and in melting had taken a death grip on the shaft. The construction of the motor was such that the head frame had to be taken off to get the box out. To get the head off (and with it the box inside) it became necessary to use two 6 ft. bars to hitch the frame around the shaft slightly and another one to pry it off at the same time. Having got the box off, it had to be rebabbitted and bored out. Instead of sending it to another shop we decided to do the job ourselves, motor or no motor. Having foreseen all this when the babbitt was first discovered "seized" to the shaft we had the mandrel and molten babbitt all ready by the time the motor head was off. Likewise one of the idle men had prepared a lathe for boring the box, and as the helpers were mostly idle, they stood by readly to supply "mule power" to the lathe. This they did in relays, and so quickly, that in a little more than three hours we were running again. We couldn't have beaten this if the job had been sent to another shop.

AN EXPANDING ARBOR.

By D. O. Barrett.

THE expanding arbor shown was designed for handling cast iron gear blanks, of which we have a great number to machine. The blanks are turned all over preparatory to having the teeth cut on a Farwell gear hobber. They are first caught in a universal three-



Expanding Arbor.

jaw chuck, bored and reamed to the proper size, and also faced down one side, which is also stepped; afterwards being put on the expanding arbor shown, turned to the proper diameter, and faced to thickness.

The arbor is held in the lathe spindle and driven merely by the fit of the taper shank. It was at first thought that under heavy cuts it would become loose, but no trouble was experienced from this source. The body is turned to the bore of the blank, with a shoulder at the back. It is also bored to take the stud, although this would not necessarily extend entirely through. The front is tapered out and split with eight slots, while fitted inside this and over the stud is a tapered washer, which may be pressed in by means of the nut on the stud. Back of this washer, which is hardened, is a heavy coil spring to force the same out when the nut is released. In order not to interfere with the tool when facing down the side, the body of the arbor does not come quite through the blank.

The heavy lines in the cut, of course, indicate the gear blank.

SPLIT NUT GRIPS.

By T. R.

INSTANCES innumerable in which lathe work has to be performed on finished studs and bolts occur in all machine shops. Thus, bolts already screwed may require their heads reduced or faced or studs may have to be shortened or re-chased. To drive such a job in the lathe, the common practice is to screw two nuts on the thread and lock them; the lathe dog for driving the bolt or stud being clamped to the lock nuts, which thus protect the thread. However, this method is not always available. The threaded portion of the stud may be too short to take the two nuts, or the stud may be threaded larger than standard in order to fit some hole that has worn large through constant usage. In such cases other means must be devised, and the following method has proved thoroughly satisfactory.

Take a standard nut and with a hacksaw cut right through the centre of the hole. File the faces of the two halves smooth, and chamfer the edges of the thread to remove any burrs left by the saw. The two half nuts can then be clamped to the stud by the lathe dog. If the time taken to so clamp them be compared with the time taken to run on and lock two nuts, the advantages of the split nut method will be at once appreciated, especially where the studs or bolts are over size. Such split nuts are well nigh indispensable and should be kept readily accessible in every toolroom.

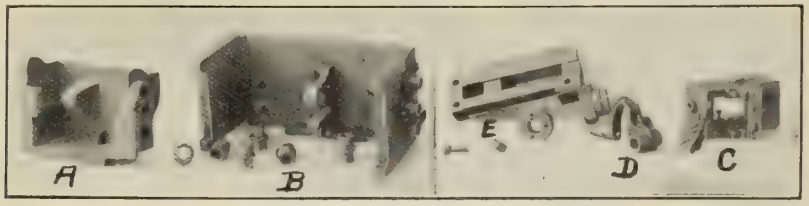
JIGS FOR A QUICK CHANGE GEAR CASE.

By E. W. Tate.

ILLUSTRATED herewith are the jigs used in machining a quick change gear device. The gear case (A) contains seventeen holes excepting the lock pin holes, all of which are drilled through

the jig (B) at one setting, and (C) is the jig used to drill the lever (D).

The jig (E) is used to drill the bed to which the gear case is attached; thus avoiding the necessity of holding the case, which varies in weight from about



Jigs For Quick Change Gear Case.

fifty to two hundred pounds according to size. All parts of the cases are interchangeable; the same number of jigs being used to machine a large case as well as a small one.

THE LOCOMOTIVE MAINTENANCE PROBLEM.

THE visitor at the locomotive shops of English railways may notice a practice which conduces greatly to economy and efficiency of locomotive repairs. He will see a number of complete boilers on hand for the different types of locomotives used by the road. For the most numerous types there may be five or six. When an engine comes in for heavy repairs, the old boiler is lifted off and a new one put in its place, so that the locomotive spends only a few hours in the shops, instead of the three or four weeks usual in this country.

Advantages Accruing.

There are some very decided advantages to this practice in addition to keeping locomotives continuously in service. Figuring the value of a locomotive's time on the basis of its share of the entire earnings of the road—which we believe to be the correct method rather than using the mere interest on the investment—the loss of time in the shops amounts to more than the labor and materials used in repairing. On the other hand, the expense of carrying on hand extra boilers is only the interest on the investment, and this is more than compensated by other advantages. Work done in a hurry or under pressure of any kind is expensive and rarely thorough. By taking time to repair and to build boilers, the work in the shops can be equalized, a smaller force is kept steadily employed without overtime, inspection can be made thorough and everything runs smoothly. It is better for the men and better for the company. This is worth far more than the interest charge on extra boilers.

Any material reduction in the time which locomotives spend in the shops reduces the locomotive investment necessary to do the business of the road. In cases of emergency, such as the long-continued cold weather through which we have recently passed, or such a congestion of freight business as took place in 1907, the advantages of quick repair are enormous. The accumulation of crippled power at such times accentuates the congestion and it not infrequently leads to placing orders for large numbers of new locomotives beyond the normal requirements of the road.

The facility of making repairs also removes to a considerable extent the temptation to keep locomotives in service when they ought to be undergoing repairs. Locomotive failures and breakdowns are enormously expensive, although the cost of delay and detention of traffic cannot be figured with mathematical exactness. One railway system of which we know has a considerably higher cost of locomotive maintenance than some neighboring roads with similar conditions. It ascribes this to the policy of keeping its power in first-class condition at all times, thus ensuring regularity of service and decreased cost of operation, although at higher repair cost.

Comparison of Locomotives.

European locomtives are better built. They cost more, but they stay out on the road doing their work, instead of spending 20 per cent. of their time in the shops. Boilers are built so as to be interchangeable; one can be taken off and another put in its place, without making new attachments and refitting. American locomotive boilers are not built with such accuracy. It is doubtful whether on any given lot of locomotives supposed to be exactly alike, an exchange of boilers could be quickly made. Such accuracy has not been deemed necessary, and, as it is supposed, at least, to cost more money it has not been aimed at. It is doubtful, therefore, whether with existing locomotives the English practice could be used. There is no doubt, however, that this lack of interchangeability is costing American railways an immense amount of money.

If there is to be no change in future practice, the number of types of locomotives will continue to increase, and each engine will be, as now, an individual machine instead of a member of an interchangeable class. This is not the only cause of growing cost of maintaining them, but it is an important one. The way toward decreased cost of maintenance and increased efficiency of operation leading to reduced transportation cost, lies in reducing the number of classes of locomotives on a road, and complete interchangeability within the class. The argument that this would hinder improvement through invention and design is fallacious; though it would prevent an enormous amount of expensive experimentation which never pans out.

We apprehend, also, that ultimately the cost of that accuracy which would be necessary to secure such interchangeability would not be as great as it is now claimed. It would not involve "building a locomotive like a watch"—although there are many reasons for believing that the road of truest economy lies in that direction. Orders for fifty or more locomotives of the same type and design are not infrequent in ordinary times. It would be interesting to learn just how much more would be charged for the necessary accuracy, and what would be the final economic results of a fair and sympathetic trial of the foreign practice we have mentioned. —The Railway and Engineering Review.

PANAMA CANAL MACHINERY.

COL. Goethals, engineer in charge of construction of the Panama canal, in a report, states that over $15,000,000 worth of machinery has already been purchased in connection with the work. Some of the principal items are:—Steam shovels, 102; cars, 4,181; locomotives, 189; rock drills, 725; cranes, 79; dredges, 14; barges, 44. After the canal is placed in operation, many of the locomotives and cars will be continued in use, but the remainder of the equipment will be put up for sale.

Secretary of the Interior Fisher has suggested that much of the Panama canal machinery be transferred to Alaska for use in constructing a government railroad to the interior of that territory. It will be necessary for Congress to authorize the building of this road, however, before this plan can be considered.

PREVENTION OF RAILWAY WRECKS.

MR. W. T. B. McDONALD, of Granby, P.Q., has invented an apparatus designed to prevent accidents such as that which occurred at Montreal, Windsor street station, a few years ago, when a passenger train dashed into the buffer, causing considerable loss of life. The arrangement is shown in the accompanying illustration. An inverted channel is placed on the rail for a distance of 100 feet; the section of rail and channel being seen in the left hand lower corner, fig. 1. To the inverted channel the special buffer is attached; thus the 100 feet of channel with the buffer on top is free to slide along the main track. As the train approaches the buffer it reaches the superimposed channel, and runs along this until it hits the buffer, when the force of the blow causes the whole upper track to slide on the lower, bringing the cars to rest with a minimum of damage.

It is claimed that a train with an engine and 10 coaches, like the G.T.R. International Limited, can be brought to rest in 40 feet when traveling at 40 miles an hour. A formal and successful test was made on Monday, July 22nd, when an engine and 10 cars bumped hard; it was of course, impossible to test under emergency conditions. The C.P.R. and the Grand Trunk are both considering the adoption of the device.

There is a piston rod with a semi-spherical end located at a proper height to be struck by the coupling. The blow forces the piston in, and compresses the air, thereby setting up a resistance. It also creates a vacuum at the other end, which assists the compression. Valves are arranged at both ends.

STEAM V. ELECTRICITY FOR RAILWAY TRACTION.

JUDGING from the opinions of railway men so far expressed, it appears safe to say they are practically unanimous that for frequent uniform suburban services, electricity has already proved its superiority over steam for railway traction. Mr. E. B. Maitland, in a discussion at a graduates' meeting of the Institute of Mechanical Engineers, pointed out that "for services where there are many miles between successive stops and where a considerable time elapses between the passage of successive trains, the use of the steam locomotive permits of advantages which are unattainable with any electrical system of traction. It is obvious that for long lengths of track, both the first cost and maintenance charges for electricity will be considerably greater than those for steam; because not only are there the cost of the transmission lines, examination and repair of same, but also those of sub-stations and auxiliary machinery. Again, as there are far fewer trains than on the previously mentioned suburban services, the stand-by charges at power and sub-stations is proportionately increased.

The greatest point in favor of the steam locomotive with regard to ease of manipulation and traffic working, is, perhaps, its independence and freedom from sectional break-downs. It is also probable that before the electrification of our main lines could take place, the whole system of their commercial management would have to be changed, as they could only be run with anything like true economy by using district power stations, each supplying all the lines within a certain radius, so that what are at present separate railways would receive their current supply from the same nuclei. For short branch lines where there is light traffic, there seems little doubt that the self-contained steam coach has come to stay. For main lines, the whole question seems to be one of coal consumption; and with the modern steam locomotive, which the author believes is by no means incapable of further improvement, especially when superheating shall have been universally adopted with its attendant saving in coal and boiler maintenance, it will be very hard to prove its inferiority in this respect."

Max E. Duncan, who was recently connected with the American Car and Foundry Co., St. Louis, Mo., has associated himself with the Canadian Car and Foundry Co., Montreal.

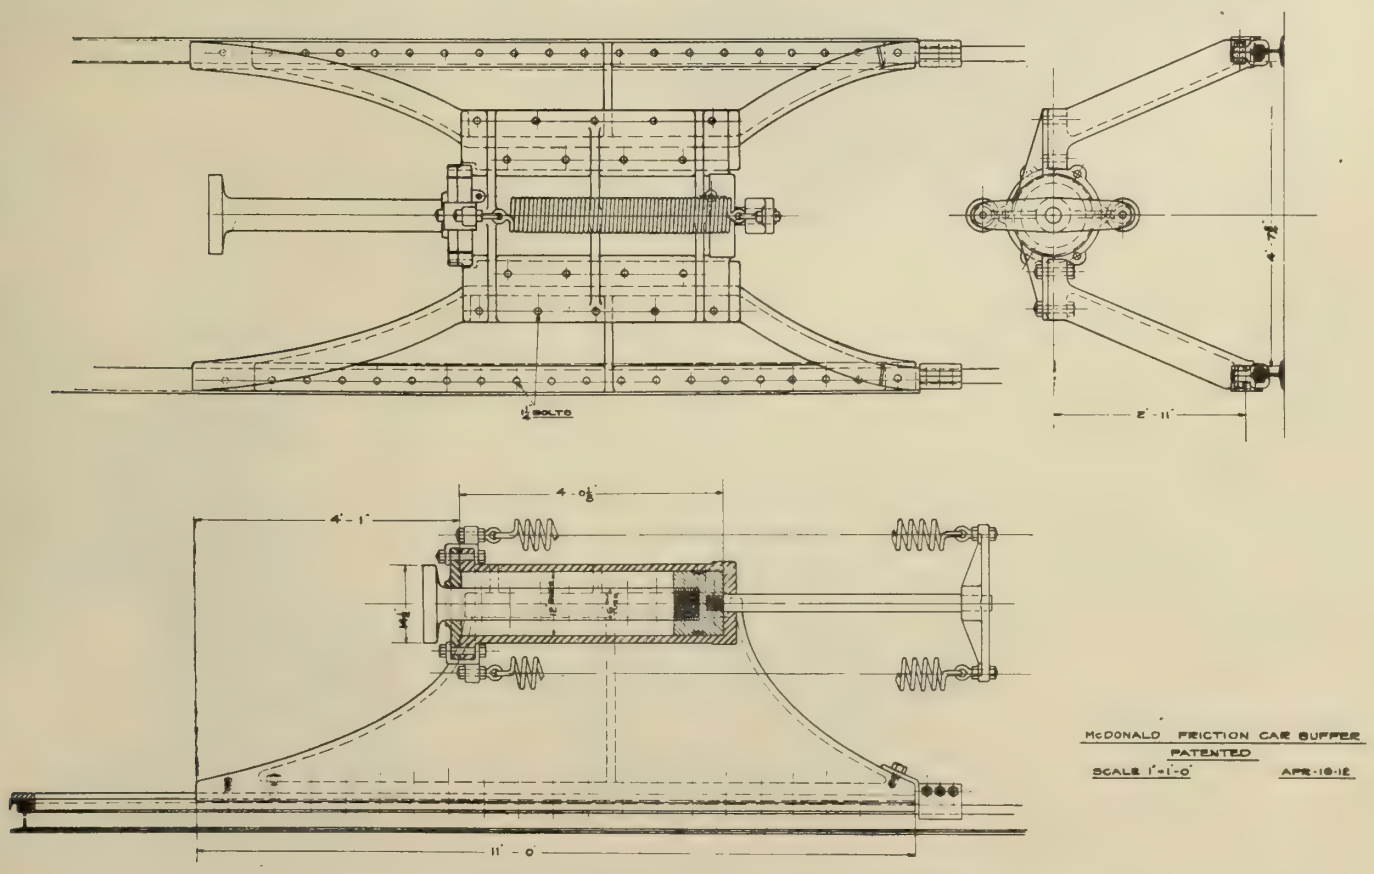


FIG. 1—PREVENTION OF RAILWAY WRECKS.

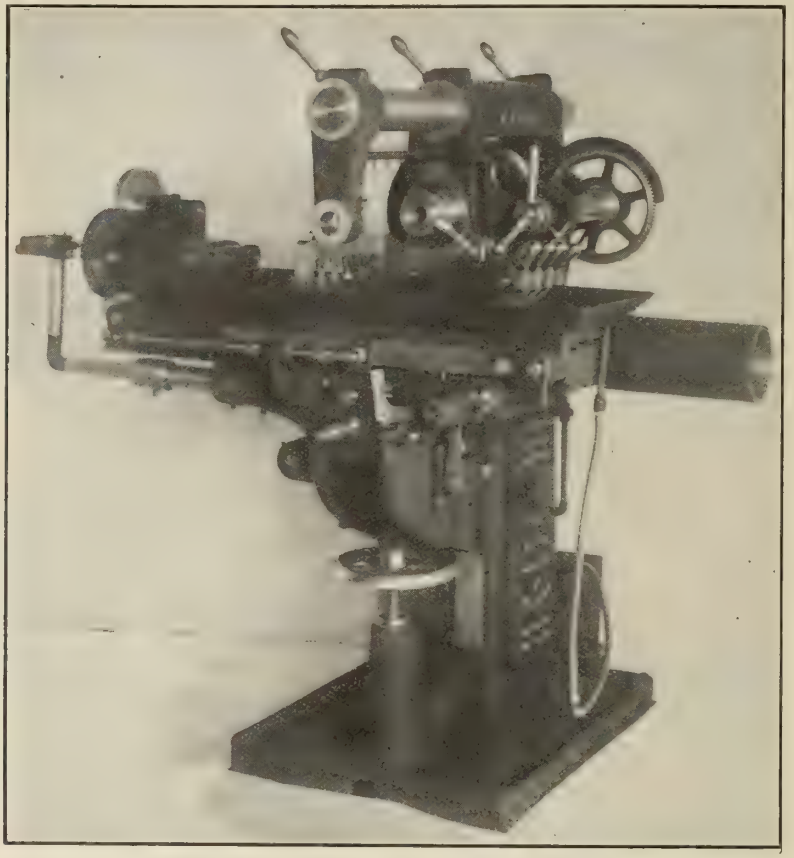
DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

AUTOMATIC INDEX MILLING MACHINE.

THE machine shown in the illustration is what is known to the trade as the No. 13½ Automatic Index Milling Machine. It is used for the automatic fluting of taps, reamers, the cutting of gears, ratchets, etc., and is adapted to the automatic and economical performance of repetition work. The modifications introduced comprise quick acting, work holding apparatus, automatic index, automatic feed with quick return by a long spring checked by an air cushion, and automatic stoppage of the machine when the work is completed.



AUTOMATIC INDEX MILLING MACHINE.

On finishing the cut, the machine is tripped by a dog shown to the left on the table, which releases the latch, allowing the worm to drop out of mesh with the worm gear. The table being now free from the power feed, rushes back to the other extreme of its travel by a spring enclosed in a tube at the rear of the table. This rapid motion is checked before the table reaches its fixed stop by the air cushion shown to the right of the machine. At the same moment that the dog trips the machine, the stop collar shown on the screw along the front of the table comes in contact with the bracket and trips the tilting table by means of the cam shaft, thus allowing the return of the work without the cutter dragging. As the table approaches the extreme return position, the right hand dog on the table strikes the stop plunger, bringing the worm back in mesh with the worm gear at the moment the table comes to rest. The bringing of the worm in mesh with a worm gear has been practised for the past fifty years for starting and stopping the feed of numerous machines.

When the table comes to rest, the right hand stop collar shown on the screw along the front of the table lifts the tilting table back to its work position and also lifts the index pawl so that the dial can index, and lets it fall back instantly. The machine is now ready for another cut, and this operation will keep up until the work is finished. The mechanism will trip again, and on indexing, the projecting pin on the index dial will push the corresponding sliding pin on the telescope bar—shown on the extreme left of the figure, and knock off the eye of the rope connecting with the spring on the countershaft, stopping further operation.

The machine will take 16 inches between centres, and a cut of 7½ inches long can be taken anywhere in this distance. The centres have a capacity for holding work on all four spindles up to 2 inches diam., and on the two outer spindles up to 4 inches diam. The machine weighs 2,200 lbs., and is an addition to the Automatic Index Milling Machine Line of the Garvin Machine Co., Spring and Varick Streets, New York City.

MULTIPLE KEY SHAFT GRINDING MACHINE.

THE new multiple key shaft grinding machine, illustrated herewith, is designed to grind with a formed wheel simultaneously the side of two keys and radius between an integral multiple key shaft, or sliding gear shaft for an automobile transmission case. Liberal bearings, massive proportions where greatest strength is required, centralized location of operation, together with highly skilled labor in the construction of every detail, contribute to produce a machine of high efficiency, giving accuracy of finished product.

Constructional Detail.

The vertical column is provided with two wide bearings, to which the grinding wheel head is gibbed. The column is substantially ribbed internally and is

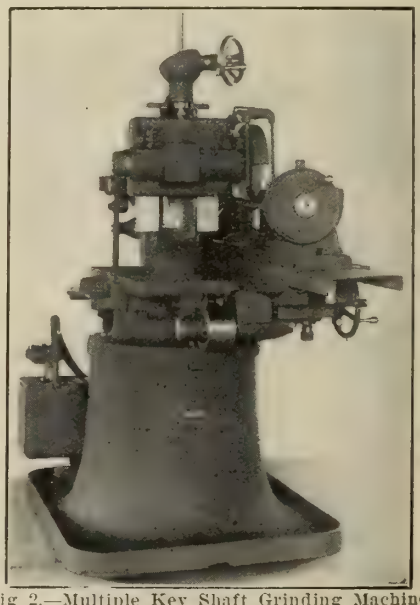


Fig 2.—Multiple Key Shaft Grinding Machine.

firmly bolted to top of base of machine, forming a massive unyielding unit. The grinding wheel head is of the most rigid construction. The wheel spindle is made of tool steel hardened and ground, and runs in large adjustable phosphor bronze bearings, thoroughly protected from grit. In the design, careful attention has been paid to the oiling system. The hand wheel which feeds the grinding wheel vertically is graduated to read to .00025 inch, and is provided with a stop for duplicating work. The thrust of the screw is taken by a ball thrust bearing.

The machine is provided with a semi-automatic indexing work-head, substantial in construction and firmly bolted to the table. The indexing mechanism consists of an index dial, a tooth ratchet wheel and an index plunger bolt, all of which are protected from water and grit. The index plunger bolt is automatically released by a slight backward movement of handle, and by a forward movement, the work is revolved and the plunger bolt engaged in next tapered notch. This mechanism is so designed that the dial cannot revolve backwards when free of the plunger, which insures positive action of indexing. The number of divisions on dial are determined by number of keys on shaft to be ground. The footstock furnished on this machine is very compact and rigid in construction. The centre carrier is flat, and set into the base at an angle, bringing the centre within ½ inch of top and ½ inch of inner side of footstock. This allows the grinding wheel to pass over or by the footstock, without disturbing setting of grinding wheel. The centre carrier is operated by a spring, controlled by a lever, shown at right hand end of footstock. The carrier may be locked firmly in position by handle shown at left hand end of footstock. All operating parts are thoroughly protected from water and grit.

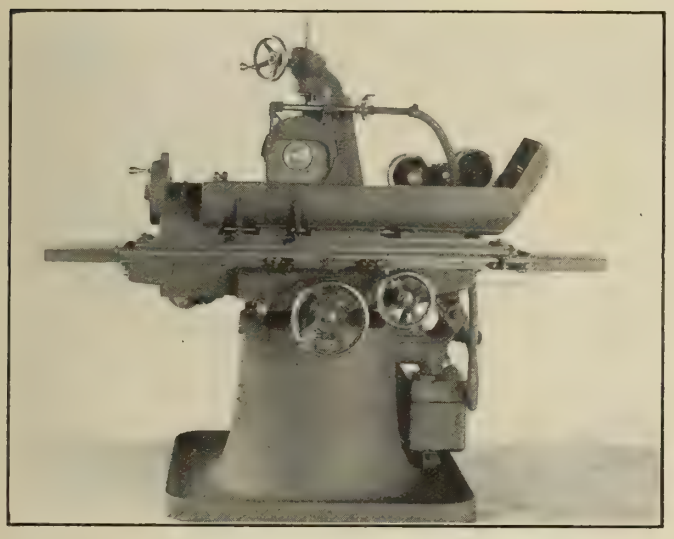

Fig. 1.—Multiple Key Shaft Grinding Machine.

Wheel Trueing Device.

The wheel trueing device is provided with three black diamonds, one for forming radius of wheel and operated by a short lever shown at end of fixture; the other two diamonds are for forming the sides of wheel and are operated simultaneously by long lever shown at end of fixture. The diamond for forming radius is carried by a steel spindle which revolves in a tapered bearing, and is provided with a very sensitive adjustment. The alignment or side forming diamonds are insured by adjustable tapered keys. It is intended that when this device is properly located back of the footstock, it will not be disturbed. When trueing the grinding wneel, the table is moved so as to bring centre of grinding wheel over centre of diamonds. The table is provided with a twin stop for locating correct position.

The master block for setting diamonds is clamped on top of wheel trueing device base, which is provided with a dovetail to insure alignment. The master block carries a hardened tool steel plug to which the diamonds are set. A shield is furnished to cover bearing on wheel trueing device when master block is not in use. A combination centering and rest base for centreing work with rapidity, and on slender work to act as support, is furnished. This fixture is clamped to table and is provided with a plunger, the top of which is formed to fit between two keys of the shaft to be ground. The plunger is actuated by a spring and controlled by a lever which has a cam cast integral and engages plunger. A slight turn of this lever to the left relieves plunger of shaft, or when used as a support for shaft, plunger may be clamped firmly in position by moving lever in opposite direction.

The table is controlled by adjustable dogs operating against the reversing lever which actuates the clutch of the load and fire type, or through conveniently located hand reversing lever which provides means for stopping the table at the end of its traverse automatically, by giving the lever a part of a turn at any time during the traverse of the table. All operating levers, handles and adjustments are within easy reach of the operator from the front of the machine. The water tank is separate, making it convenient for cleaning and the pump requires no priming or packing. The countershaft has self-oiling, self-lining bearings.

The Bath Grinder Co., Fitchburg, Mass., are makers of this machine.

A LIGHT UNIVERSAL MILLER.

HEREWITH is illustrated a No. 2 light universal milling machine, especially adapted for tool room work or light manufacturing, which possesses several points of interest. As may be seen, the top of the column is spread out to take a special flanged support, which is bolted to the column seat, affording a wide bearing for the overhanging arm, and giving the latter stiffness and increasing the cutting capacity. This is a patented feature of the miller.

Vertical milling and slotting attach-

ments can be supplied with the machine; the former is seen at (A) Fig. 2, and the latter at (B). These attachments are not driven by the main spindle, but

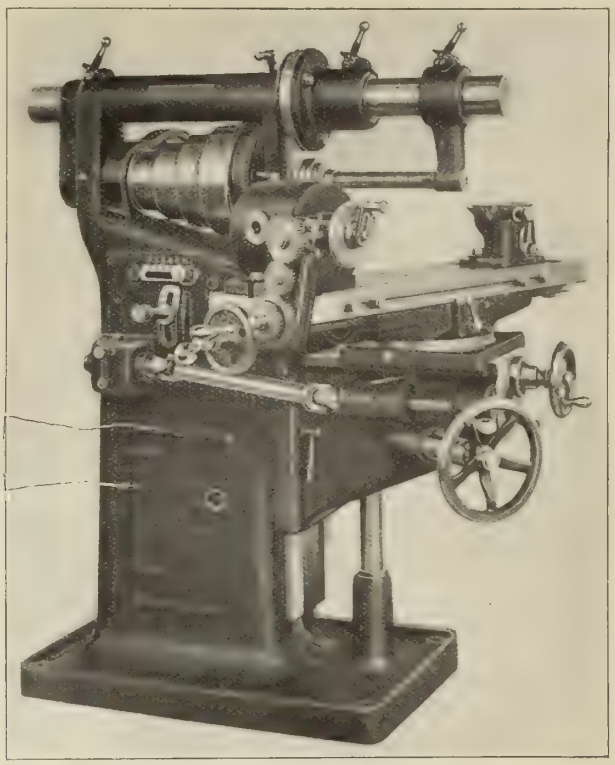

Fig. 1 Rockford Milling Machine.

on the contrary can be operated simultaneously with it. To use either, the overhanging arm and its flanged support are removed and the attachment substituted. The latter is driven by the special shaft shown at (C), Fig. 2; this shaft being geared to the back end of the main spindle, as seen at (D). When the main spindle only is in use, it is not always necessary to remove the attachment, since the latter can in many cases be swung round to clear the work. Either attachment can be rotated through a complete circle, the flange being graduated in degrees. The interesting manner of driving the attachments above indicated allows the full capacity of the machine to be utilized. The miller has automatic power feeds 25 x 7½ x 19 inches, while the main spindle has 16 speeds ranging from 22 to 309 R.P.M. There are 14 feed changes provided, all positively driven through gearing and capable of being operated and reversed while the machine is in motion.

The universal indexing head swings 10½ inches, and is fitted with an extra large worm wheel, 5⅜ inches diameter. The worm runs in an oil bath and can be easily disengaged from the worm wheel for quick indexing. This miller has been put upon the market by the Rockford Milling Machine Co., Rockford, Ill.

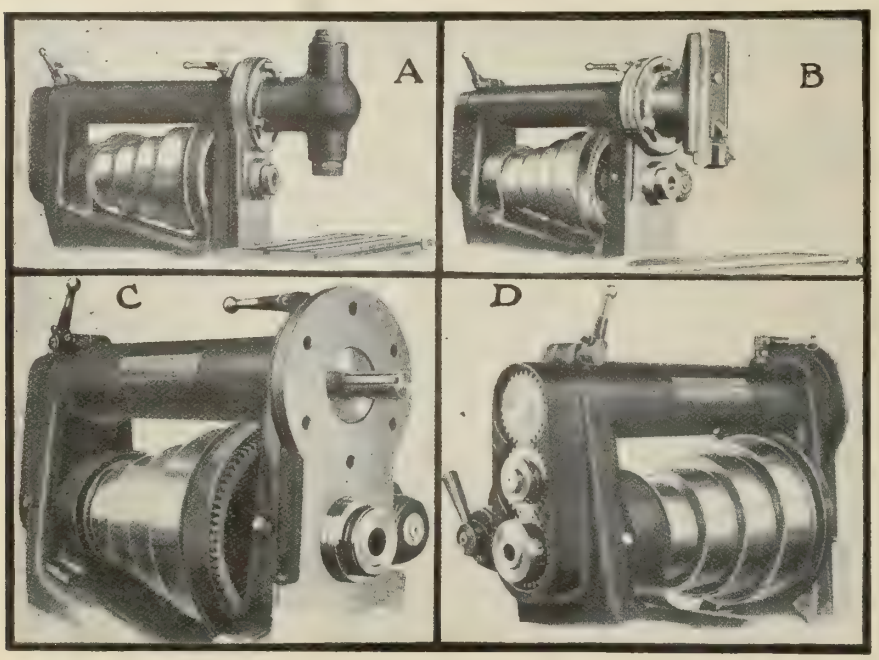

Fig. 2. Rockford Milling Machine.

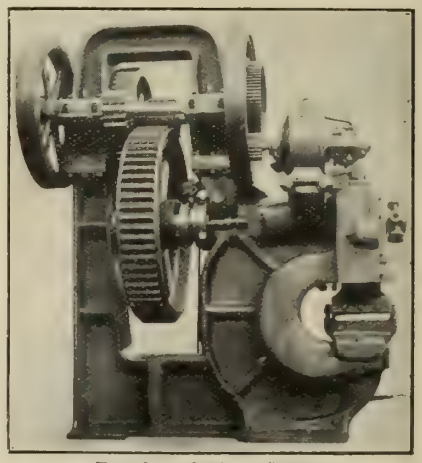
PUNCH AND SHEAR PRESS

ECONOMY of floor space, always an important item, is particularly so in a machine shop when it is desired to install additional tools. The accompanying illustration will indicate how this may be effected in the case of a motor-driven punch and shear press, made by the Cleveland Punch and Shear Works, Cleveland, Ohio. The arrangement of overhead gearing renders it possible to make a very compact unit, and one, thereby, economical of floor space. The machine complete with its motor weighs approximately 50,000 pounds, and is designed for heavy work, having sufficient capacity to shear twelve inch lengths of 1½ inch flat bars, and to punch a five-inch hole in 1½ inch plate. The various attachments such as those for angle shearing, bar shearing, and punching are interchangeable. The motor of 25 horsepower capacity at 230 volts, is of the well-known direct current, commutating pole type, specially adapted for this kind of work by the Westinghouse Electric Manufacturing Co.



Punch and Sheer Press.

The Peterborough Engineering and Constructing Co., Peterborough, Ont., is about to be reorganized as a joint stock company. The plant is now being equipped with up-to-date machinery, and will have facilities for handling all kinds of repair work, more particularly the manufacturing of special machines of every description. Mr. P. H. F. Spies, formerly master mechanic with the Peterborough Shovel Co., is manager; Mr. F. S. Schneider , president, and Mr. G. F. Schneider, secretary-treasurer.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

SWEEPING OUT AN OVAL MOLD.

By J. H. Eastham.

THE rubbing plate for marble polishing purposes shown at Fig. 1 was required cast in halves, as indicated in sketch. Half an inch extra stock being

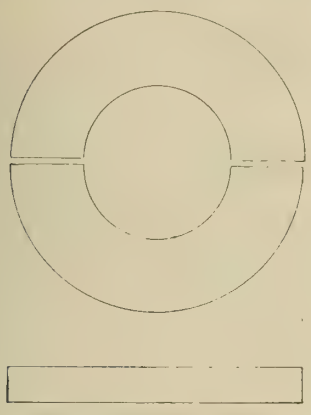


Fig. 1—Rubbing Plate.

ordered on each casting at the joints, and flat cores 3 inches thick being used to split the piece, an oval or elongated mold was of course compulsory.

As no pattern was available; the job being of the occasional variety, the spindle and sweep were resorted to, with the method of procedure as follows:—Two ordinary 2-inch spindles were clamped together exactly parallel at 4 inches centres; a special foot or centre being afterwards chilled round them. This casting, indicated at Fig. 2, was now bedded dead level in the foundry floor some six inches below the full depth of the mold, (A), Fig. 3. A spindle (B) was next mounted as shown, and the board or sweep (C) bolted to position; the straight or plain edge downward, so as to strike out a bed on which to ram-up the cope. The spindle was then removed, a layer of parting sand spread over the bed, and the cope rammed-up and hoisted away with runners and risers in their proper places.

Two half circles, the outside 1 inch wider and the inside 1½ inches narrower than full size of the plate, were now marked on the bed; the space between them being afterwards dug out 1 inch deeper than the finished mold. Following this operation the inside was lined up with facing sand; the sweep, with face or drag side downward, being then employed to strike out the bottom or drag impression, half the plate being struck from one hole in the centre piece and half from the one opposite, as shown at Fig. 4.

The space between the halves was now made good. A small section pattern was employed for the purpose and the gates cut. The mold was afterwards plumbago blackened, the splitting or division cores placed in position, and the cope lowered to place. Plan and sectional views of the finished mold, Figs. 5 and 6 show the types of gates and risers employed; a quick flow of hot metal, low in phosphorus and moderately low in silicon with careful feeding through risers 5 inches diameter giving excellent results when the castings were machined.

LAYOUT AND PATTERNMAKING OF BEVEL GEARS.

D. O. Barrett, M.E.

IN the January issue of this publication, the writer presented a method of laying out and accurately forming the teeth of patterns for spur gears. The following discussion is along the same lines, but applied to bevel gears, and it is desired to show the layout and necessary calculations for determining the shape of the tooth in such a manner that it can be readily applied by any one without resorting to complicated calculations.

Differential Gears of a Traction Engine.

The gears shown in Fig. 1 were encountered in the design of a traction engine; being the differential gears of same. There are four pinions set into the body of a large spur gear, and these transmit the entire power of the engine to the larger gears at either side. Each of these latter is rigidly connected to the driving pinion on that side, and the arrangement serves to allow one of the driving wheels to travel ahead of the other, as when turning a corner; yet insuring an equal amount of power being transmitted to each. All the gears are steel castings. The pitch diameter of the gear is calculated as for spur gears, having chosen the circular pitch and the number of teeth. However, the tooth contour does not conform to that for the same number of spur teeth.

	GEAR.	PINION.
PITCH DIAM.	22.282	3.980
NO. OF TEETH.	56	10
CIRCULAR PITCH,	1.25	1.25

Fig. 1—Differential Gears of a Traction Engine.

The pitch surfaces of spur gears are plain cylinders, whilst the pitch surfaces of bevel gears are portions of cones which have a common vertex—the point of intersection of the shafts. The tooth shape is laid out on the surface of a cone whose slant side is perpendicular to the slant side of the pitch cone. The angles (a) and (b) are called the centre angles, or angles of the pitch cones of the gear and pinion respectively. These two angles are complements of each other, that is, their sum is equal to 90 degrees. The backs of the teeth are laid out perpendicular to the pitch or centre line and continued until they intersect the centre lines of the gears as (MN) at (C), while the intersection of the centre line (OP) comes without the limits of the drawing. Now, this distance from the point of intersection of the pitch line as at (A) to the respective centre line is the determining radius for which the tooth shapes are calculated. Fig. 2 shows the complete layout with the necessary dimensions. The distances (OS) and (SA) are one half the pitch diameters. (OA) is the pitch line or intersecting line of the pitch cones. (CAP) is drawn perpendicular to this, and intersects the centre lines at (C) and (P). It is necessary to determine the lengths (CA) and (AP).

The distance (OA) is found by the solution of the right angle triangle.

$OA = \sqrt{(OS)^2 + (SA)^2} =$

$\sqrt{(1.99)^2 + (11.141)^2} = 11.371$ in.

Now the triangles (OSA), (ASP) and (CAO) are all similar right angle triangles, and consequently the sides are proportional.

We may, therefore, write:

OS : OA : : AS : AP

$$OS : SA : : CA : OA$$

$$\text{or } \frac{OS}{OA} = \frac{AS}{AP} \text{ and } \frac{OS}{SA} = \frac{CA}{OA}$$

$$\text{or } AP = \frac{AS \times OA}{OS} \text{ and } CA = \frac{OS \times OA}{SA}.$$

$$\text{Substituting, } AP = \frac{11.141 \times 11.317}{1.99}$$

$$= 63.358 \text{ inches, and } CA = \frac{1.99 \times 11.317}{11.141}$$

$= 2.021$ inches.

The distances 2.021 and 63.358 are the radii of pitch circles that determine the number of teeth from which we obtain the desired shape. The teeth from now on are laid out as simple spur teeth, and the number corresponding to the radius of 63.358 will be

$$\frac{2 \times 63.358 \times 3.1416}{1.25} = 318.$$

Turning to the table in the January issue, we find the constant for 318 teeth to be 6.88, which multiplied by the circular pitch gives $6.88 \times 1\frac{1}{4} = 8.55$, say $8\frac{1}{2}$ inches. The base circle will be $63\frac{3}{8}$ (which is sufficiently close) times $0.968 = 61\frac{3}{8}$, approximately. The tooth is laid out at the side of the gear, all the other dimensions being obtained as previously shown. Of course, the centre (P) may be found graphically by extending the perpendicular (AP) until it intersects the centre line (OP), but the calculations may be performed by any one who is familiar with square root, and if not, tables giving square roots are readily obtainable.

Proceeding in the same way for the pinion, we find the radius to be 2.021, which gives slightly over 10 teeth. The nearest whole number must, of course, be used, and the calculations made for this number. We now have the actual shape of the teeth at the outer end, and it only remains to produce them in the pattern. Of course, these cannot be

cut by a formed cutter as with the spur gears, on account of the shape continually changing; the sides gradually converging to the centre (O). It will be noticed that the larger teeth are drawn with a single curve.

A block, preferably of maple (Fig. 3), is now cut out as at (JA), the length

Fig. 5—Layout and Patternmaking of Bevel Gears.

of the tooth to be formed. The large end of the tooth (A) should have the shape as laid out in Fig. 1. However, it would be rather inconvenient to lay this out here, and, better than this, a shape can be laid out on each end of the block, so that the desired form shall be produced at (A). To do this, lay out a diagram as in Fig. 4, where (OA)

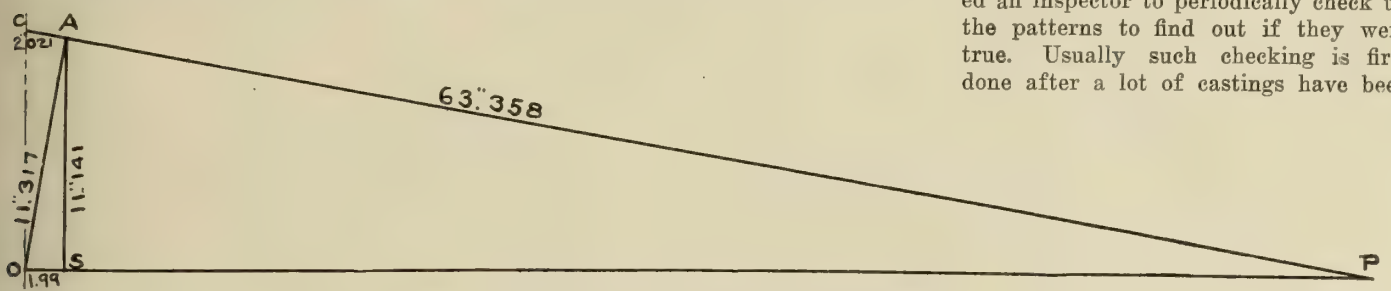

Fig. 2—Layout and Patternmaking of Bevel Gears.

corresponds to the distance (OA) of Fig. 3, (OF) to (FA) and (OG) to (AG). Join (O) to (G) and (F). These dimensions need not be the exact dimensions of Fig. 3, but may be some fraction of same, as long as all remain in the proper proportion. Take any dimension on the actual tooth profile and lay out along the line (OA), as (OX). Draw a line through (X) parallel to (FG); then the distance (XZ) is the length to be laid out on the end (G), and (XY) the length to be laid out on the end (F).

Correspondingly, enough distances may be taken so that the shapes can be accurately laid out at each end when the block may be readily tapered from (G) to (F), so that all the lines drawn along the sides would converge at (O). The teeth are cut to the proper length and inserted in the block, being held by the two screws at the bottom. It is best to rough them all out by hand to somewhere near the proper shape before finally finishing.

A wooden cylinder is now turned up as in Fig. 5; about the same length as the formed block for holding the teeth. In the centre a portion is turned slightly smaller so that when a strip of sandpaper is glued to it the surface of the paper will come even with the ends of the cylinder. The length of the paper is made just a little longer than the teeth. The rough teeth are now inserted in the holder, and they can be readily sandpapered to the exact shape, as the ends of the cylinder will bear against the ends of the formed block and prevent the teeth being cut lower than the block. If the teeth are worked out to nearly the desired shape, the process of sandpapering requires but a few minutes. Of course, it is not possible

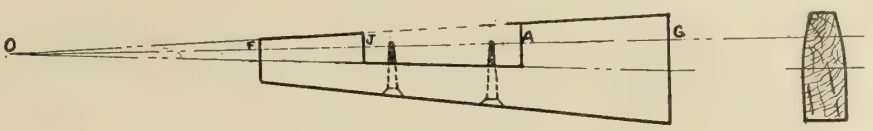

Fig. 3—Layout and Patternmaking of Bevel Gears.

to have the fillet at the bottom part of the tooth by setting same into the body of the gear, as was done with the spur tooth, because the sandpaper cylinder will not get into the smaller circle.

The teeth can be very rapidly formed by this method; the most accurate part of the work being the shaping of the block in which the teeth are held, be-

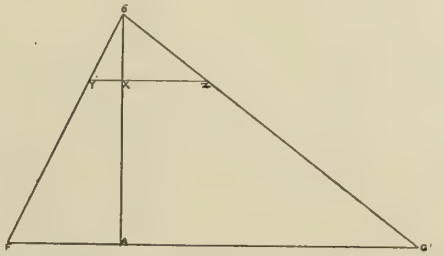

Fig. 4—Layout and Patternmaking of Bevel Gears.

cause the teeth will be reproductions of this shape. To get the proper angle at which to turn the body of the gear where the teeth are held, a side view of the pattern should be drawn, as in Fig. 1.

PATTERNS FOR THE FOUNDRY.

IN an address before the Superintendents' and Foremen's Club at Oakley, Cincinnati, Ohio, Mr. H. M. Ramp, superintendent of the Modern Foundry Co., called attention to the difficulties the foundryman has to meet because of the fact that patterns are poorly made or in poor condition. In the course of his address he said that many concerns have inspectors who check up every piece of work done in the factory; some have inspectors who check up every gage and templet at stated periods to discover errors and prevent mistakes; but he knew of no concern that employed an inspector to periodically check up the patterns to find out if they were true. Usually such checking is first done after a lot of castings have been rejected, and only then is the pattern found to be at fault.

There seems to be a tendency to-day to save on pattern cost, although a great deal of money is spent for improved machinery in the machine shop to improve the quality and cheapen the cost of the finished product. The average patterns in the average foundry to-day are not made as well as they were ten years ago, and still there is a reason why the foundry ought to be supplied with better patterns than formerly. The trend of the times is to reduce the skill of the workers by putting more dependence on improved machinery; hence the molders of to-day are not as skilled as they were years ago, and, for that reason, better patterns rather than poorer ought to be the rule.

Mr. Ramp also called attention to the lack of understanding of the requirements of the foundry on the part of many machine designers. The castings designed may be perfectly fitted for the purpose for which they are made, but the design is such that the molder cannot make a perfect casting on account of the excessive strains produced by the unequal proportions of the different

parts, and it is impossible to prevent these castings from cracking or warping. It is easy enough to say that no more metal is required at this or that point; it may be very creditable to be able to design a machine with a maximum of utility and a minimum of weight, but, nevertheless, there are unalterable laws in the shrinkage or contraction of cast iron that the designer cannot be permitted to overlook. Many castings are designed with a view to saving metal, which, as a matter of fact, will have a higher ultimate cost than if no specific effort to save metal had been made. The extra labor cost in the foundry in such cases outweighs the saving in the cost of the metal.

CRUCIBLE STEEL FURNACES.

THE increased life of furnaces used for melting crucible steel, due to the careful supervision which is now being given this class of work, has been again demonstrated by the record of a 24-pot furnace in operation at the works of the Colonial Steel Co., Monaca, Pa. This furnace was in continuous operation from January 19, 1910, until March 20, 1912,—a period of twenty-six months and ten days, during all of which time the gas was on and the fire kept in the furnace. Steel was melted every day with the exception of Sundays, fifty-two Saturdays and eight days in the month of July, 1911; making in this period 3513 heats. The total weight of steel melted was 9,274,320 lb., of which 924,000 lb. was high speed steel, the remainder consisting of carbon tool steel and special alloy steels, such as chrome nickel, chrome tungsten and 30 per cent. nickel steel. The total cost for repairs was about $20.

BELT INFLUENCE ON MOTOR OUTPUT.

By Geo. P. Pearce.

WE had supplied a double disk mill to a large grain company whom we will call the Smith Flour and Grain Co.; also two 10 horsepower motors to drive it. Our customer said they could install the outfit and that they would furnish the two 8-in. belts for driving. They stated the number of bags of meal required per hour and did not wish us to send larger motors than necessary, as the central station charged a certain minimum per month based upon horsepower installed. We had found by experience that 10 h.p. on each side would just exceed the amount they asked and, therefore sent this size motors.

It was not long after the machinery had been shipped that we received quite a sharp letter from the Smith Flour and Grain Co., saying that they had installed the machinery exactly as shown on the blue prints, but they were unable to grind even half as much as we had claimed and that the outfit was useless to them in this state. They got electricians up from the central station, who, after a very careful test, found that the motors were o.k., but recommended that the two 10 h.p. units be replaced by two of 20 h.p. The Smith Flour and Grain Co., were of opinion that we did not know much about our own business, by installing a total of 20 h.p., when the actual requirements were at least a total of 40 h.p. The writer was bidden go and investigate the trouble. Upon arrival, I first made a trip to the central station and asked to see the records of the test. The electrical engineer, there, was very sarcastic in his remarks about theoretical calculations being all right sometimes, but when it came to grinding machinery there had to be plenty of power, and as the motors installed would never be of any use, the quicker we put in two of 20 h.p. each, the better it would be all round. The test record certainly appeared to uphold his statement.

I then went on to the mill and was received with the cheerful information that it was up to me or the firm to make that drive right at no cost to them. I examined the mill equipment and motors and found the installation O.K. Everything was in line and level. It was rather a dark place. I started the mill, and while it started up all right, I noticed it acted sluggishly, so I shut down and went into the basement to see the motors. The wires were amply large and all connections were tight. I decided, however, to try each part separately to find out the source of the extra friction, and pulled off a few of the boards that enclosed the belts. This had been done to prevent the windage of the high speed belts from carrying dust from one floor to another. I reached in to take hold of the belt, and in doing so got a surprise, for it seemed to me that the belt was ½ inch or more in thickness. I secured a light, and there, through the hole, saw the trouble —a heavy 8 in., three-ply stiff leather belt. I asked the man who was holding the light, why on earth they bought such a heavy belt to go over 10 in. and 12 in. pulleys, running nearly 5,000 feet per minute? He said it was part of the old 16-in. engine belt that they had used before changing over to electric drive, and that they had sawn it in two to make 8 in. widths out of it.

I went to the office and told the manager that the belts were the cause of all the trouble, and that if they would get suitable belts I would prove to them that the outfit would turn out the amount guaranteed. He only laughed and said that changing belts was not going to make all that difference; that the belts installed were of the highest grade and had cost a pile of money when new. Further, they had not been used much, and had given splendid service when on the engine. It was no use calling his attention to the fact that the smallest pulley on which it formerly ran was 48 in. diameter, while that in the present instance was only 10 in. I could get no satisfaction except that if I wanted to try any "stunts" before ordering the bigger motors I could go ahead at my own expense, and that I had better hustle, as they wanted cracked corn and meal at once. I was also informed that if they had to wait very much longer he would rip it all out and I could ship it back, there being a competitor with a complete outfit ready to instal at the word "go," with a guarantee on penalty to get results. I telephoned a big belt concern in the next city to send me down by express an 8 in. light double rawhide belt long enough for both machines.

The belting came in the afternoon, and I had both on in an hour, nicely laced with wire lacing. We started up and the mill rose to full speed in ten seconds. I started grinding right away, and for three hours I ground at a good 10 per cent. in excess of the guaranteed rate; at the end of which time, the motors were not more than warm. The manager had gone home without making any comment; I, however, got the miller to sign a report to the effect that he had seen the mill doing 10 per cent. better than the guarantee without sign of overload on the motors. There was no further trouble from that day to this, nevertheless, the manager put up a strong kick before he paid for the new belts, adding that he hadn't much opinion of a machine that required a special kind of belt before it would work. The saving every month on his minimum rate, by having these small motors, did not appeal to him; but, then, some people will kick anyway.

ELECTRIC LOCOMOTIVES.

ONE great advantage of electric locomotives is the way in which, provided the line voltage is maintained, they can be relied on to develop their full power at any time, not having to depend on the state of the boiler, the skill of the fireman or the quality of fuel available. From the point of view of adhesion or grip of the driving wheels on the track rails, the motor has an advantage over the steam engine in that the torque exerted is quite uniform; for this reason there is not the same ten-

dency to slip when starting under load. There is said to be as much as 20 per cent. difference between the adhesive properties of the two kinds of engine. This effect is counterbalanced in practice owing to the steam locomotive being for other reasons made heavier than an electric locomotive of the same draw-bar pull, but only at the cost of the power necessary to move the additional weight.

The electric locomotive can be designed to have exactly the correct weight required to give sufficient adhesion at its rated draw-bar pull. It can, moreover, in the face of any abnormal demand, take advantage of the greater adhesion to be obtained by sanding the track rails, as it is able to draw power from the line and to exert a torque at its driving wheels up to the utmost limit of adhesion. This the steam locomotive cannot do, because it has no reserve power to draw upon.

ANALYSIS OF ACCIDENTS IN A MACHINE SHOP.*

By Luther D. Burlingame,
Providence, R.I.

IN making a study of safety methods and safety devices, an analysis of the accidents that have occurred in one of our large machine shops may be of service for still further protecting the workmen when engaged in their various lines of employment.

A careful record of all accidents in the works of the Brown & Sharpe Manufacturing Co., has been kept during the last seven years and a study made for the purpose of ascertaining where danger is greatest, also what accidents are preventable and how best to avoid them. It may be said that in this factory extra care has been taken for many years to guard against accident, and the management has never hesitated to spend money for that purpose when convinced that it would bring about safer conditions. During the last year an additional effort has been made to profit by past experience both at our own works and by the experience of others, and still further to tune up the safety equipment and spirit of the organization in order that accidents might be reduced to a minimum.

Method of Procedure Adopted.

When this additional work was undertaken, about a year ago, an analysis of all accidents which occurred during the previous six years was made along three lines: (a)—The percentage of accidents under each of 18 headings from different causes; (b)—the percentage by departments of the shop, divided into more than 30 groups; (c)—the seriousness of the injury and the resulting length of disability from work. Following this, a similar record, (d)—is being kept each year showing what kinds of accidents are increasing and what kinds are being decreased by the further safety methods employed, also which departments are reducing their accidents and which are growing worse.

Classification of Accidents.

The different kinds accidents were classified as follows, the percentages given being for the six years preceding the date of the investigation—1905 to 1910 inclusive:—

	Total Accidents	%
Caught in machinery	78	7
Caught or struck by belt	23	2
Set screw or other projection	29	2.6
Falling on or striking workman	226	20.1
Workman falling or strain lifting	75	6.7
Machinery starting unexpectedly	8	0.7
Chain or rope slipping or breaking	10	1.0
Punch press, rolls, or shears	20	2
Cutters and metal saws	94	8.5
Handling work or chips—eyes.	126	11.2
Woodworking machinery	47	4.2
Burns, including electricity	79	7.0
Cuts with sharp instruments	20	2
Jams and hammer blows	71	6.3
Caught in tool and work (not cutters)	176	15.7
Elevator	4	0.5
Fooling	13	1.2
Litter or dark places	15	1.3

These accidents naturally divide into two groups: (1)—Those caused by machinery either (a) by being caught in the gearing, belting or other parts of the machinery, or (b) through being injured by the cutter or other tool or caught between the tool and the work; (2)—Those caused by falling, jams, burns, cuts, etc. The first group includes 42.7 per cent. of the accidents occuring during the six years, divided as follows: Group (a) 12.3 per cent; group (b) 30.4 per cent, leaving 57.3 per cent as the proportion of accidents occurring under the second group.

Machinery Guard Features.

From the above analysis it will be seen that if complete guards were provided to prevent every accident due to being caught in gearing, on set screws, or anywhere in the mechanism of machinery, it could at most only reduce the accidents 12.3 per cent. Several recent occurrences show unexpected accidents. A workman hearing a rattling in the knee of a milling machine he was operating, reached his hand underneath to see if the cause were due to a collar which he thought might have become loose, and stuck his finger into the running gearing.

Another case was that of a workman who reached for a can of oil which he had left on a ledge of the machine. In lifting it up he caught a finger in the pump gears back of the guard. Both of these accidents occurred on machines considered sufficiently guarded, and to experienced workmen, yet they indicate that to have complete safety it may be necessary to enclose all gearing entirely, whether or not it is exposed.

A way of preventing accidents through being caught by set screws or other projections, is to insist on the wearing of short-sleeved jumpers and avoid loose clothing, hanging neckties, etc. One of the apprentices at the Brown & Sharpe Manufacturing Co., works was injured recently by having the pocket of his jumper catch on the set screws of the revolving dog while he was filing. All of the boys running machines at this plant are obliged to wear short-sleeved jumpers and the men are advised to do likewise. Seventeen of the accidents reported were due to being caught by the sleeve of the jumpers. The company is now experimenting with various forms of safety dogs, none with projecting set screws having been added to the equipment during the last year. The plan of changing the regular dogs, for headless screws adjusted with a socket wrench, is also being tried experimentally.

Guards Sometimes Undesirable.

The accidents in group (b) are more frequent and more difficult to guard against. It is practically impossible in many cases to do guarding at the point of cutting, and if guarding is attempted it may introduce dangers greater than those sought to be avoided. It is, however, possible to insist that the fingers shall never be used to wipe off chips, etc., from a running cutter. Out of the 94 accidents from cutters reported, 30 were caused by being caught when wiping off chips with the fingers.

In the use of punch presses, 20 accidents had occured in the period investigated, so this was one of the first matters to be considered. The means adopted for guarding against these accidents were novel, as far as the author is aware, and have proved entirely successful both in avoiding accidents and in preventing an appreciable increase in cost of doing the work. A rule was made that the fingers and hands must never be put between the punch and die. Tweezers and pliers were furnished for handling the work, the points being shaped in some cases to suit particular jobs. The only accidents since have been to the points of the tweezers and pliers. Chutes have also been used to slide the work into position, a stick being used to remove it after the operation. For some work which it was thought could not be handled by the above means, a swinging fixture was designed so that the job can be put in place away from under the punch and then swung into position for the operation.

*Presented before the April, 1912, meeting of the Providence Association of Mechanical Engineers.

The 47 accidents from woodworking machinery were largely cuts from circulars saws, but included eight where the block of wood was thrown back when slitting, two of the cases being fatal, the only fatal accidents in the works during this period. The men are now required to wear a heavily padded apron when using a slitting saw, and this has, it is believed, saved the lives of several workmen. The use of a "spreader" when properly installed helps to prevent such accidents by keeping the cut from closing in back of the saw. Another prolific source of accidents which, while not serious perhaps, are painful, is in being cut by revolving grinding wheels, especially when doing internal grinding and trying the plug in the hole without running the wheel back a sufficient distance. Twenty-eight of the accidents were from this cause. A shield has been designed which automatically swings up in front of the wheel so as to protect the hand if the plug should slip.

Accidents Due to Carelessness.

Under the second group, falling, jams, burns, cuts, etc., a large proportion of the accidents are entirely within the control of the operator, either the one hurt or a fellow workman, and the remedy is largely to be found by employing careful methods. In this, however, the foreman can exercise a large influence for safety. Some specific remedies can also be applied. It was found that 37 cases of burned feet in the foundry had resulted from wearing laced or low shoes. A rule was made that Congress or other high shoes without lacing should be worn, and a supply of such shoes is kept and sold to the foundryman at about cost. This has nearly remedied the trouble. There remains, however, the liability of the iron spattering into the tops of the shoes and burning the legs when the pants are ragged. A study is being made of the possibility of using pants made of non-burnable material. About one-fourth of all the accidents are caused by weights falling on the workman and jamming or cutting either the hands or the feet, and the workman himself slipping and falling. The remedy here is to use care that safe methods are employed and that men do not take chances. Classified with these are 13 accidents traceable to "fooling," some occurring outside of working hours.

Accident Classification.

In considering the classification by departments and kinds of work, it was found that, for the period of six years, the average number of accidents was greatest in the following departments, the percentage of employes injured each year being as stated:

(a)—Grinding department, 13.8 per cent.; caused largely by cuts from grinding wheels. This has been much reduced during the past year, so that this department now ranks eighth instead of first in order of accidents.

(b)—Laborers, 10.6 per cent.; largely from injury by falling objects, jams, strains in lifting and the workman falling.

(c)—Carpenters, 10 per cent.; a large proportion of the injuries being due to woodworking machinery.

(d)—Foundry, 9.5 per cent.; due mainly to burns, also to falls and falling objects.

Then follow the various machine departments from 7.6 per cent. down to 2.2 per cent., and ending with the inspection department, the offices and the drafting department with the percentage coming down to 0. Only four elevator accidents, and these slight, occurred during the six years, a very good showing with more than a dozen elevators in constant operation.

THE ADVERTISING SECTION

Intimacy with the advertisements appearing each month in the columns of this journal ensures easy location of a manufacturer and his product by the progressive and up-to-date user of machine tools and kindred equipment. Look the pages over, and you will strengthen and widen acquaintance with the masters of your profession.

Injury Classification.

In the classification by seriousness of injury and length of disability of 1,124 accidents occurring during the period of six years covered, 382 resulted in no disability, that is, no absence from work. In 457 cases there was less than one week's absence from work. Of the remaining 285 cases, 132 resulted in between one and two week's absence; 74 in two to four weeks' absence; 51 in one to three months' absence; five in three to six months' absence; and five in over six months' absence. In addition, eight were hurt so as to cause the loss of an eye, a foot or permanent injury, two dying from the effects of their injuries. Ten men left, and no record was kept of the duration of their disability. These statistics form a good basis for future investigations looking towards a still further accident reduction.

In 1911, with an average of 4,050 employes, there were 243 accidents, or about 6 per cent. of the workmen were hurt, sufficiently to report; this on a basis of reporting slight accidents as well as those of a more serious character. Some of the added measures for safety had been in operation during part of the year, so that the gain from 6½ per cent., the record of the previous year, to 6 per cent. for 1911, indicated a gain due to such further safeguarding. A like gain was also shown in the reduced number of serious accidents included in last year's list. There were no fatal accidents, no loss of eye or limb, and more than 70 per cent. of the reported accidents resulted either in no disability or in less than one week's loss of time. In some few departments, where accidents increased during the past year, special steps are being taken to ascertain the cause and to avoid a repetition. Each accident is studied to learn the lesson it teaches as to further methods of safety. It is hoped by such means to reduce the accident list to a minimum for the benefit of both workmen and employers.

FOUNDRYMEN'S CONVENTION AT BUFFALO.

THE American Foundrymen's Association Convention to be held in Buffalo on September 24, 25 and 26 of this year promises to be at least equally as successful as its predecessors. Following the practice of former years, the Foundry Machine Exhibition Co., will have on display and in operation from September 23 to 27th inclusive, an up-to-date assortment of machines, tools, appliances and accessories relative to foundry and allied trades practice. The American Institute of Metals and the American Foundry Foremen's Association will also meet in Buffalo during the same week, hotel headquarters arrangements having already been determined upon by the various sections. Secretary Richard Moldenke, Watchung, N.J., has prepared a circular of particulars of special reduced fares obtainable on the various railroad systems and will gladly give all information. Canadian Foundrymen have a great opportunity this year of getting into intimate touch with the latest developments in their chosen profession, and every encouragemnt should be given employes of our numerous foundry plants to spend a day or two in Buffalo. Our September issue will contain full details of the convention programe together with list of exhibitors, etc.

The Dominion Metal .Co., of Sherbrooke, P.Q., have chosen rather a novel method of keeping their name before users of babbitt. They are presenting pipes to engineers who use their metals, also to a number of those who should use them. The bowl of the pipe bears the inscription, "Sold on Merit—Dominion Babbitt Metals." A large number of the fraternity have been enjoying good quiet smokes as a result.

Trade Gossip.

Mr. Lacey R. Johnson has been appointed general superintendent of the Angus shops district, C.P.R., and is succeeded as assistant superintendent of motive power by **Mr. H. Osborne**, late superintendent of the locomotive shops.

The Bawden Machine Co., Orillia St., Toronto, are erecting a factory on Stirling road, which is expected to be ready for occupancy in September of this year.

The Imperial Steel & Wire Co., Collingwood, Ont., may head an amalgamation of wire concerns, according to reports being circulated. The merger would include three independent wire mills. President J. A. Curries, president of the Imperial Co., states that there is some truth in the reports, as negotiations are under way for the acquisition of other mills by his company, but that matters are not far enough advanced for the publication of details. The Imperial Co. recently paid a 20 per cent. dividend and has enlarged its preferred stock capital by $300,000. It has no bond issue or other fixed charges and is in an excellent position to carry out the project. At a recent meeting of Canadian manufacturers of wire nails, the list of extras was changed. Everything in the 5 and 6-inch list were made the base; all in the 4-inch class were advanced 5 cents, and in the 3-inch class, 10 cents per keg.

The Can-British Engineering Co., Ltd: has been recently formed to carry on the business of an engineering supplies and construction corporation in the Dominion of Canada. It will establish branches in all the principal centres, at each of which stocks of standard appliances, spare parts, etc., will be carried. The intention of the company is to undertake contracts for the supply and erection of all classes of machinery, and to purchase the plant required, as far as possible from leading makers in the United Kingdom. The subscribed capital is $1,000,000, and in addition to a headquarters board of directors in England, a local board in Canada is also provided. This latter consists of Mr. W. A. Martin, managing director, of Toronto, late assistant general manager Toronto Electric Light Co., Mr. Ernest M. Sellon, Montreal, director of Mathews, Wrightson & Co., (Canada, Ltd); Mr. Charles Ruttan, Winnipeg, of Ruttan & Chipman, financial & commercial agents; Mr. Nichol Thompson, Vancouver (manager for Western Canada, Cammell, Laird & Co., Ltd.

The Smart-Turner Machine Co., Ltd., Hamilton, Ont., have recently secured the following orders:—The Hamilton Bridge Works Co., duplex pump; The Terra Cotta Pressed Brick Co., Ltd., Toronto, duplex pump; Lothbiniere & Megantic Railway Lyster, Que., duplex brass fitted pump; The Corporation of Dundas, centrifugal pump; The Oliver Chilled Plow Works, Hamilton, centrifugal pump; The International Harvester Co., Hamilton, duplex end outside packed plunger pump with pot valves; Rixon, Ainslie, Stoddart Co., Ltd., Owen Sound, Ont., duplex pump; Dominion Canners, Ltd., Hamilton, duplex pump; Town of North Toronto, Ont., centrifugal pump; J. S. Mundell & Co., Elora, duplex pump.

The Vulcan Engineering Sales Co., of Chicago, announce that it has taken the selling agency for the line of structural and plate working machinery,—Punches, shears, rolls ,bulldozers, etc., manufactured by the Rock River Machine Co., Janesville, Wis. This is in addition to the lines already controlled, which include the product of the Hanna Molding Machine Works, pneumatic riveters; Mumford Molding Machine Co., molding machines and foundry equipment; G. M. S. Co., metal sawing machinery and shop equipment. The Vulcan Engineering Sales Co., make a specialty of machinery for structural and boiler shops and foundries.

STEEL CASTINGS

Acid Open Hearth Steel for Locomotive and Machinery Castings.

Stock Process Steel for Automobile and Light Castings of all descriptions.

Our plant will be in operation early in October.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

Hamilton, Ont.—The Imperial Car Company, a Canadian organization, in which local financiers are heavily interested, has purchased a fifty-acre site here and will erect a plant to cost nearly a million dollars, for the purpose of manufacturing steel and wood freight cars. The company has an authorized capital of $6.-000.000.

Toronto, Ont.—The Hamilton Gear and Machine Co. has secured a permit to erect a $2,-500 one-storey machine shop at the corner of Van Horne and Concord Avenue.

North Vancouver, B.C.—The opening up of a means of communication with the large zinc deposits of the Western Dominion Land and Investment Co. at the head of Lynn Creek, gives apparent possibility that a smelter will be established soon. The plant will cost about $150,000.

Owen Sound, Ont.—Work has commenced on a nut and bolt factory which will employ about 400 hands. The plant is being built near the site of the C.P.R. elevators which were burned down last autumn.

New Liskeard, Ont.—It is understood that the Wabi Iron Works Company will re-organize and establish a new foundry on a site adjoining the railway tracks. A considerable sum of money has been put into the business by outside parties and the prospects are sufficiently bright to ensure at least fifty men being employed.

Halifax, N.S.—Fire recently did damage to the extent of between eight and ten thousand dollars at the plant of W. and A. Moir, engineers and machinists. All the patterns were destroyed. Loss is covered by insurance.

Sydney, N.S.—The Dominion Coal Company are making a big addition to their car shops at Glace Bay. They have also recently completed the erection of twelve miners' houses and three officials' residences at the Birch Grove Collieries.

Port Colborne, Ont.—The Canadian Union Furnace Company have started work on their large plant here. They have let contracts totalling close to half a million. The plant is expected to be finished by the close of the present year.

Sarnia, Ont.—The work of building the new street car barns for the Sarnia Street Railway has been started by the contractors. The buildings will be constructed entirely of concrete blocks and will have a gravel roof. A separate machine shop will be built for making repairs to cars. The cost will be over $12,000.

Hamilton, Ont.—Work has been commenced on the plant of the National Car Company and will involve an outlay of $300,000. The promoters recently gathered at Montreal and appointed the following officers:—President, Sir John M. Gibson; Directors, J. J. Scott, K.C., William Southam and Basil Major. The principal building in connection with the plant will be 200 by 520 feet, and this it is expected will be ready for occupation by October the 15th.

Welland, Ont.—The Metal Chemical Company, Limited, are about to locate an electric smelter plant here, together with ten acres of land adjoining the chosen site. The following men are behind the venture:—J. W. D'Angero, M. E. D'Angero, J. H. Charles, and G. W. Vaness.

Fort William, Ont.—W W Butler, of the Canadian Car and Foundry Company has opened temporary offices here and will undertake at once the direction of the million dollar car foundry about to be built.

Sherbrooke, Que.—H. G. James architect, Sherbrooke, has prepared plans for the construction of a foundry, boiler and machine shop for the Sherbrooke Iron Works Co. A. G. Campbell is manager.

Owen Sound, Ont.—The Northern Bolt & Screw Co. will call bids shortly for the erection of a new factory 83 x 220 ft. J. H. Cole is manager.

Georgetown, Ont.—The Georgetown Foundry Co., Charles Young, manager, will have plans prepared at once for a large iron foundry.

Edmonton, Alta.—Morehouse & Nesbitt, Jackson Block, Edmonton, have prepared plans for the erection of a new machine shop and foundry to cost $60,000 for the Western Foundry & Machine Co. Benjamin Olsom is general manager.

East Kildonan, Man.—The Grigg Mfg. Co., Minneapolis, Minn., will build a new $100,000 plant for the manufacture of farm implements at East Kildonan.

St. John, N.B.—The management of the Union Foundry and Machine Works are making preparations to enlarge the plant to a considerable extent. Mr. George H. Waring is president and manager of this concern.

Prescott, Ont.—The Grand Trunk Railway has signed a provisional agreement to move its shops from Brockville to Prescott; also to make the latter town a divisional point. The agreement was executed by the mayor for the town, and by its terms, the municipality is obliged to meet certain named conditions. No difficulty is expected in voting the required by-law on the part of the ratepayers. The anticipated change will be a boon to the city of Prescott. The railroad proposes to proceed at once with the building of a repair shop and roundhouse.

Brockville, Ont.—A carriage company has begun the manufacture of automobiles. The machine is called the Atlas. The motor, wheels, chassis, and nearly all other parts are imported from the United States and assembled in Brockville. The body of the car is manufactured at the local shops.

Welland, Ont.—B. J. McCormick, Industrial Commissioner, announces the location in Welland of the Northern Steel Co., Limited, with a capital of $1,200.000. It will erect rolling mills for rolling sheets and black plate. The main building, 150 feet by 600, 85 feet high, will be equipped with a ten-ton crane. Other smaller buildings will be erected on the property. The construction of the plant will begin at once, with the object of opening in February. The only concession granted the company was fixed taxation. It will locate in the southeastern port of the town, on a portion of the Kennedy property, and will have switches from the Michigan Central, Wabash, Grand Trunk, T. H. & B., and Canadian Pacific Railways. Fifteen acres of land have been purchased. There was considerable competition to secure this plant from other towns and cities which were offering bonuses, bond guarantees, etc, but the cheap power and the close proximity to Pittsburg, giving cheap rail freight rates, and allowing a low cost of production, were a combination which secured the mills for Welland. W. R. Glasgow, formerly Works Manager of the Canadian Steel Foundries, Welland, will be general manager. The present offices, which are in the Traders Bank Building, Toronto, will remove to Welland as soon as construction begins.

Windsor, Ont.—The White Machine Works Limited has been incorporated with a capital of $40,000 to manufacture and sell all kinds of saw mill and planing mill furnishings, sharpeners and machinery in general, with head office at Windsor. The provisional directors are A. E. White, of Eau Claire, Wis., E. S. Wigle, barrister, and Dr H. R. Casgrain, of Windsor, Ont

Montreal, Que—Aberdeen Estates Limited have been incorporated with a capital stock of $250.000 to carry on business as contractors, builders, electricians, mechanical engineers, etc., with head office at Montreal. The incorporators are A. H. Duff, W. A. Merrill, and R. Burnett, advocates, all of Montreal.

U.S. RAILWAY BUSINESS FOR MAY

FOR the month of May, the net operating revenue of U.S. railways declined five and five-tenths per cent. per mile of line as compared with May 1911, and that for May 1911, was four and eight-tenths per cent. less than for May 1910. This is the salient fact of the monthly summary of the Bureau of Railway economics, compiled from the reports of the railways to the Interstate Commerce commission, and embracing ninety per cent. of the steam railway mileage of the country.

The total operating revenues were $226,109,262, an increase of $7 per mile of line over May, 1911. The operating expenses were $161,368,677, an increase of $24.29 per mile of line, while the net operating revenue was $64,740,585, a decrease of $17.23 per mile of line. Taxes amounted for the month to $9,897,301, or $45 per mile; an increase of nine and two-tenths per cent.

The decrease in net operating revenue was most severe for the Eastern group of railways, amounting to eleven and nine-tenths per cent. For the Southern group it increased four-tenths of one per cent., and for the Western group less than one-tenth of one per cent. The aggregate of the net operating revenue for the eleven months of the fiscal year, and also for the five months of the calendar year, when measured per mile of line, shows a decrease in comparison with the corresponding periods of the previous year.

PATENTS GRANTED.

BELOW will be found a list of all patents recently granted in Canada relating to mechanical engineering and iron and steel foundry practice, furnished by Fetherstonhaugh & Smart Castle Bldg., 53 Queen St., Ottawa, Canada.

141,477.—Thos. Edwards, Ballarat, Victoria.—Tilting roasting furnaces.

141,483.—S. Gibson, Porcupine, Ont.—Beat propulsion.

141,484.—Thos. W. Green, Philadelphia, Pa.—Rotary blowers.

141,485.—Thos. W. Green, Philadelphia, Pa.—Divided impellers for blower.

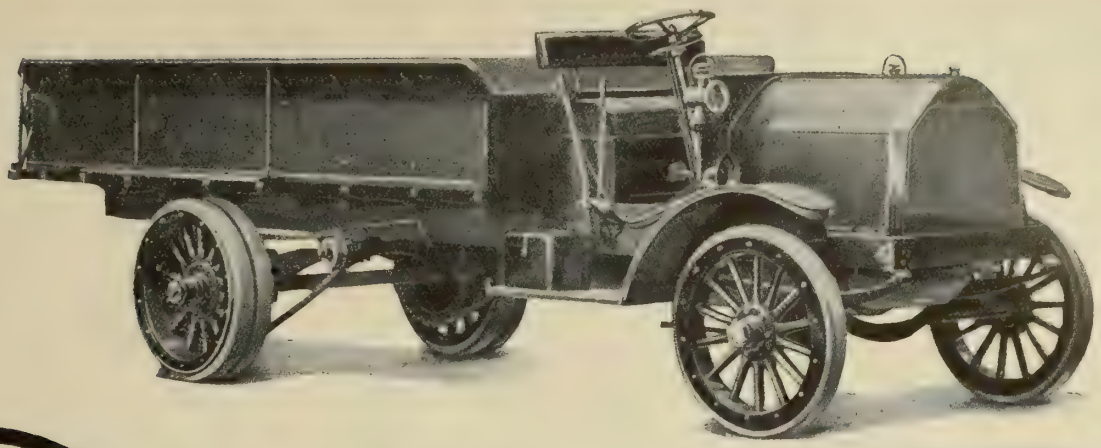
141,490.—S. Hato, Seattle, Wash. —Display apparatus.

141,493.—D. H. Henderson, Baldwinsville, New York.—Shaft couplings.

141,495.—P. Jorm, Hamburg, Germany —Railroad track scale.

141,506. — Wm. C. Martyn, 23 Alma Road, St. Kilda, Victoria, Australia.—Tractors.

141,508.—Jno. T. Metcalfe, Quincy, Pa.—Friction clutches.



Have You Heavy Goods to Handle?

If you have Machinery or any Heavy Lines of Merchandise to deliver you can Save Money

by using Schacht Heavy Duty Motor Trucks

Built for Canadians with Canadian Money.

How One Truck Saves $2204.80 Per Year

Cost of Equipment and Operation of One 6-Ton Truck for Five Years

Capacity: 144 tons per day.

1 Six-ton truck	$ 5,500.00
Gasoline averaging 36 miles per day, 300 days per year, at 6 miles per gall. (16½c. per gall.)	1,485.00
Oil at 50c, 120 miles to the gallon	225.00
Grease average at 15c pound, running 1 lb. to 100 miles	81.00
Repairs and repainting, $75.00 per year	375.00
Tire replacement average 8,000 miles per tire (150 per tire)	4,200.00
Oil for lamps at $20.00 per year	100.00
Incidentals at $25.00 per year	125.00
Liability and Fire Insurance $150 per year	750.00
Driver at $2.50 per day; $780 per year	3,900.00
License at $2.00	10.00
Depreciation at 20 per cent	5,500.00
Interest at 6 per cent.	1,650.00
Battery charging at 50c per month	30.00
Total	$23,931.00

Cost of Equipment and Operation of Four Teams and Wagons for Five Years

Capacity: 120 tons per day.

4 Teams at $500.00	$ 2,000.00
Coal wagon at $225.00	900.00
Harness at $40.00	160.00
Wages of drivers at $2.00 per day	12,000.00
Repairs to harness $10.00 per set	200.00
Feed, Vet. services, stabling, shoeing, etc. at $25.00 per horse per month	12,000.00
Repairs to wagon at $25.00 per year	500.00
Insurance 2 per cent. on horses and wagons	305.00
Interest on investment at 6 per cent.	1,830.00
Depreciation on wagons and harness 2 per cent. per annum	1,060.00
Depreciation on horses 40 per cent. per annum	4,000.00
Total	$34,955.00

SUMMARY.

Total cost of maintenance and operation of 4 teams and equipment for 5 years	$34,955.00
Total cost of maintenance and operation of one six-ton truck for 5 years	23,931.00
Total saving in 5 years	$11,024.00
Net annual saving in favor of the six-ton truck	$ 2,204.80

BEST LEATHER BELT MADE

THE J.C. McLAREN BELTING CO. OAK EXTRA TANNED EST 1856

TORONTO MONTREAL WINNIPEG
ST. JOHN, N.B. VANCOUVER

Edmonton, Alta.—Edmonton is to have a new industry in the shape of a brass foundry, which will be in operation by the fall, according to Mr. Solsbaug, of the Boston firm of Clark & Solsbaug, who is now in the city completing arrangements for the purchase of a site. This firm has been in communication with the board of trade for some time and from information given by the secretary of that body, has decided that Edmonton is a most favorable spot in which to locate a growing industry.

Battleford, Sask.—That Battleford secures the location of The Eby Foundry Company plant, is the announcement made recently by Commissioner A. A. Leslie. This company will erect a modern foundry and moulding plant. The site selected is the property immediately adjoining the Battleford Iron Works Co. premises on the west, which location affords excellent trackage and easy shipping facilities.

MUNICIPAL.

Saltcoats, Sask.—The electric light by-law calling for an outlay of nearly $20,000 has received the sanction of the ratepayers.

Melfort, Sask.—Three money by-laws totalling $125,000 for waterworks, sewage disposal and electric light were carried unanimously.

Saskatoon Sask.—The by-law to raise $500,000 for the construction of a street railway system received the sanction of the ratepayers.

Blyth, Ont.—The waterworks by-law to raise $5,000 by debentures for expenditure in laying water mains and consolidate the overdraft from 1911 has been passed.

Wainwright, Alta.—A by-law for the erection of a $25,000 flour mill was carried.

Outlook, Sask.—The ratepayers have decided to raise $15,000 by debentures for the purpose of installing an electric lighting system.

Fernie, B. C.—The ratepayers rejected an electric extension by-law.

New Westminster, B. C.—The ratepayers recently passed seven money by-laws aggregating in all $1,190,000: Harbor, $500,000; Street, $250,000; Gas Plant, $225,000; Hospital, $100,000; Waterworks, $75,000; Parks, $25,000; Storehouse, $15,000.

Ottawa, Ont.—The by-law to raise $66,500 re construction of new water mains recently received the assent of the ratepayers.

Humboldt, Sask.—A by-law was passed by the ratepayers whereby $8,000 will be raised as a loan to the Carberry Sash and Door Factory.

Fort William, Ont.—The burgesses passed the following by-laws:—To bonus the Canada Car & Foundry Company to the extent of $250,000; $253,000 re extension of water works system; $200,000 for street railway extensions; $14,000 re fire system; $57,000 re agreement with A. M. Hanton; and $16,000 re bonus to Great West Wire Fence Company.

Chilliwack, B. C.—The ratepayers recently passed the waterworks by-law.

Owen Sound, Ont.—The two industrial by-laws recently received the assent of the ratepayers. They provide for the raising of $20,000 in aid of the Superior Match Company.

Berlin, Ont.—The ratepayers voted in favor of raising $25,000 to bonus the Canadian Consolidated Rubber Company.

Halbrite, Sask.—The council have authorized the issue of debentures for $3,000 re aid to the tin tub factory.

Parkhill, Ont.—The waterworks by-law whereby $25,000 will be raised received the endorsement of the burgesses.

Gananoque, Ont.—The town is to have a new drill hall. A parliamentary appropriation was made at the last session and the contract, amounting to $13,000, has been let to John Dillion.

Humboldt, Sask.—The contract has been let to A. E. Pike for the erection of a new town hall here. The price is $29,150. This will include the entire work except the cost of a few cut stones which will be supplied by the city.

Kerrisdale, Point Grey, B. C.—The committee of the council has confirmed the award of the large sewerage contract to Messrs. McLean and Company at $156,000. Provision is made for the work to be completed within seven months

ELECTRICAL

Regina, Sask.—Fred H. Everett has commenced operations on the erection of a new warehouse and grist mill and will operate it by electric power.

Quebec, Que.—The power plant of the Quebec and Jacques Cartier Electric Company at St. Gabriel de Brandon was completely destroyed by fire recently. The loss is about $50,000.

Vancouver, B. C.—The British Columbia Electric Company recently called tenders for dismantling a number of old brick buildings on Pender street here, but since then, plans

have been changed, and it is now proposed to remodel the old buildings and turn them into stores and offices. The company are also building a sub-station which will be ready for service by the end of August. The total cost of building and machinery will be $125,000.

Woodstock, Ont.—A grand celebration marked the occasion of the turning on of the Hdro-Electric lights here recently by the Hon. Adam Beck. The lights are five globe standard, and Woodstock is now lighted similarly to Toronto, Hamilton, and Londoa.

Saltcoats, Sask.—The ratepayers have of late voted $20,000 toward the installation of an electric lighting system.

Galt, Ont.—The sum of $45,000 was recently voted by the burgesses toward the cost of the completion of the Hydro-Electric system.

Kingston, Ont.—Following the arrangements made between the Gananoque Board of Trade, Town Council and Gananoque Water Power Company, each to assume one-third of the estimated cost of $500 to have an engineer make calculations on the amount of electrical power that can be generated by the Gananoque River for use as motive power by the manufacturers of the town, Engineer Robertson, of Montreal, has been at Gananoque and Marble Rock making estimates.

Sasaktoon, Sask.—By the latter part of September the capacity of the Saskatoon power plant will be 5,077 horse power. There recently arrived from the Allis-Chalmers Company, of Milwaukee, a new steam turbine engine and four cars of boilers. This new equipment will add to the capacity of the power house, 3,000 horse power.

St. Mary's, Ont.—Chairman Weir, of the water, light, and heat commission, reports many applications from farmers for power and light since he made public announcement that the board was prepared to give power and light to all farmers within the corporation limits.

Toronto, Ont.—The city council has instructed the city architect to prepare plans and specifications for the erection of a municipal abattoir and cooling plant. An expenditure of $300,000 is proposed.

Winnipeg, Man.—Ratepayers of Winnipeg, Man., will vote on a by-law to provide $750,000 for extensions to the power and light distribution system of the city. H. N. Ruttan is city engineer.

Welland, Ont.—Welland recently turned on the power in the new waterworks plant, which was built at a cost of $75,000, and is a model of its kind. It is entirely apart from the old plant, but both will be kept in commission. The new plant has a capacity of three million and a half gallons daily and is arranged so that it can be increased to ten million gallons daily.

Fredericton, N.B.—For some years enterprising men of this community have believed that there were great power possibilities at Mednctic Falls on the St. John River about 40 miles above Fredericton. Last winter a company headed by a St. John capitalist, incorporated the St. John River Hydro-Electric Co. to develop this power. A Canadian hydraulic engineer has inspected the dam site, and plans are under way for immediately developing 10,000 horsepower, which will be sold along the St. John Valley, particularly in Fredericton and St. John. With cheap power, industrial expansion may be expected.

Calgary, Alta.—Applications by the city of Calgary to construct an $8,000 electric light substation, and by the Wilson Furniture company for a $66,000 warehouse were the principal items at the office of City Building Inspector Sylvester, recently.

Kingston, Ont.—The Seymour Power Co. purposes making another proposal to supply power to Kingston. It has had experts here looking over the ground, so that the offer will be as fine as can be drawn.

Brockville, Ont.—At a special meeting held recently, the town council authorized the mayor and clerk to sign a contract with the Ontario Hydro-Electric Commission for the transmission of cheap power to Brockville. It is expected that the power will be ready for delivery here by the first of the New Year.

GENERAL MANUFACTURING. ....

Welland, Ont.—Prof. Richardson, Toronto, of the Electro-Chemicals Co., Ltd., has arrived to lay out the ground for the new plant here, the company having purchased a plant and 15 acres of land. Buildings will be proceeded with at once.

Hardisty, Man.—A plan is being considered by which it is hoped a brick plant will shortly be established here.

Sault Ste. Marie, Ont.—Fulfilling the agreement made by the Lake Superior Pulp and Paper Company with the city, the company's mills are now being operated. If the output

Ker & Goodwin

Brantford, Canada

of the mill is satisfactory on the initial run, paper will be at once placed on the market. The expectation is to turn out about 200 tons per day.

Toronto, Ont.—Messrs. Rolph and Clark recently purchased a lot on Carlaw avenue, here, upon which it is proposed to erect buildings for a lithographic plant to cost $150,000 and to employ about 225 men.

Levis, Que.—A new industry is about to commence operations here to be financed by Canadian, French, and Belgian capitalists. The company is asking the municipality for a suitable site.

Ottawa, Ont.—A firm known as the Try Me Tire Company is about to start business on Sparks street here. The promoters are Messrs. F. B. Carling, and Eric McLaghlin of Ottawa. The principal business of the company will be the repairing of automobile tires

Berlin, Ont.—As a result of the bonus by-law recently carried here, the Consolidated Rubber Company will receive a grant of $25,000 and will commence at once the building of a $250,000 plant.

Palmerston, Ont.—Charles Kreutziger, of Waterloo, Ont., has purchased the old carriage company's property here and will start at once the manufacture of trunks. Fifty workmen will be employed.

Ripley, Ont.—The Ripley Flax Comapny has decided to run the flax mills again this season. They have from 150 to 300 acres of flax under cultivation. The plant employs during the summer about 50 persons, and in the winter about 25. During the previous season, the Ripley Flax Company manufactured from 30 to 40 tons of dressed flax, about 15 to 25 tons of green tow, and 2,500 bushels of seed.

Picton, Ont.—Six new canning factories have recently been established at the following points:—South Bay, North Port, Picton, Consecon, Wellington, and Bloomfield.

Belleville, Ont.—A new industry is about to start business here. The industry will manufacture coke and wood alcohol. It will give employment to about sixty men, and is capitalized at $500,000.

Toronto, Ont.—Owing to the civic authorities failing to complete the deal for the nursery property at the corner or King and Dufferin streets, the Toronto Carpet Company will leave the city and concentrate its efforts at Peterborough or St. Catharines. It employs about seven hundred men.

Camrose, Alta.—The Camrose Clay and Lumber Products Co. Ltd., has been fully organized and will commence at once the manufacture of pressed bricks. The company is incorporated in the province of Alberta and capitalized at $100,000. They will install a plant capable of manufacturing 100,000 pressed bricks per day.

Victoria, B. C.—Construction has been started on a cement plant at Saanich Inlet, which will have a capacity of two thousand barrels daily. It will employ two hundred and fifty men.

Guelph, Ont.—The Raymond Manufacturing Company are enlarging their building with a one-storey addition. The Taylor-Forbes Company is also enlarging their industry by an additional one-storey steel and brick building to cost $5,000.

St. Thomas, Ont.—W. E Wilson and Ernest Cummings, both formerly of Galt, are about to commence the manufacturing of shoes here. They are requesting a bonus of $12,500 from the corporation and will commence at once the erection of a factory 100 feet by 40 feet, and two storeys high. The firm will be known as the St. Thomas Shoe Company.

New Hamburg, Ont.—It is reported that a new furniture factory is to be started in New Hamburg by a number of old New Hamburgers, provided they get some inducement from the town. The men at the head of the affair are all experienced in this line of business.

Hanover, Que.—The factory of Glaiser & Leinberger, manufacturers of parlor frames, was damaged by fire, July 8. Loss $2,000.

Bridgeburg, Ont.—The Canadian Jewett Refrigerator Co., Ltd., has been incorporated with a capital stock of $50,000 by Edgar B. Jewett, John E. Jewett and Robert F. Buckley of Buffalo, N.Y., as provisional directors, and will build a plant for the manufacture of refrigerators near the International Bridge.

SAW AND PLANING MILLS.

Peterborough, Ont.—The plant and buildings of the Mann Lumber Co., have been purchased by Mr. A. H Stratton. The plant, an up-to-date one, is being put in first-class condition for operation. Some repairs are necessary owing to the recent fire. As soon as these have been made, it is expected the mill will be open for business.

FOUNDRYMAN'S WEEK

September 23 to 27, 1912

AT BUFFALO

will give parties in Canada the best opportunity they have had to attend the conventions and see the exhibits since the meeting in Toronto, in 1908. The Exhibits have doubled in size since then and will be a big attraction at Buffalo.

In the Broadway Exposition Building there will be installed the largest exhibit of foundry equipment ever made, showing the latest and best that is manufactured.

Proprietors, Managers, Superintendents and Foremen

should all plan to spend one or more days in the inspection of this exhibit alone.

This is an opportunity for the seller as well as the buyer, and if you are manufacturing or selling any article of interest to the foundry and machine shop trade you should secure space and become an exhibitor.

Application should be made at once as there are only a few spaces left.

Apply to

C. E. Hoyt, Secretary and Manager,

The Jones Safety Device Co., Ltd.

152 Dundurn St., Hamilton, Ont.
12 Waverley St., Buffalo, N.Y.

West Lahave, N.S—The wood-working plant and sawmills of Boehmr Brothers were recently destroyed by fire. The mills were among the best in the province. Damage to the extent of $60,000 was the result, and no insurance was carried.

Toronto, Ont.—Harry Hope's planing mill at 498 Concord avenue was burned a short time ago. The total damage is $3,500, of which insurance is carried to the extent of $2,625. The origin of the fire is unknown.

Kenora, Ont.—A fire entailing the complete loss of the Rat Portage Company's saw mills occurred here recently. Several thousand feet of lumber in the mill vicinity was fire swept during the conflagration. The cause of the fire, which is the worst in the history of the town for some time, is said to have originated near a bandsaw.

Nelson, B. C.—Directly the plans have been completed, tenders will be called for the construction of a new mill at the Hewitt mine at Siverton to replace that recently destroyed by fire.

Thornloe, Ont.—Fire of unknown origin recently destroyed 550,000 feet of lumber and 30,000 feet of saw logs at the mill owned by Mr. Neely. The total loss is estimated at $15,000.

Haliburton, Ont.—One of the finest saw mills in this district was recently destroyed by fire. The mill, known as the Wm. Laking Mill, was damaged to a great extent. $8,000 insurance was carried.

West Toronto, Ont.—Batt's planing mill was recently damaged by fire, the origin of which is unknown. The firemen's quick response was the means of checking the blaze before much damage was done.

Weyburn, Sask.—The Weyburn Sash, Door and Glass Company have of late opened for business. They have installed a 50 h.p. electric motor and will employ between twenty and thirty men.

Collingwood, Ont.—The tug Balize arrived from Shawanaga with a raft of logs numbering over 50,000 pieces for the Kent-Cooper Co. The mill began running and will continue until the fall.

Bathurst, N. B.—J. Bennett Hochey, of Bathurst, bought the large shingle mill here together with the rights to cut cedar over certain properties, also a large block of timber lands for the sum of $17,000.

Toronto, Ont.—A fire, which did damage to the extent of $1,500, broke out at the J. C. Gilchrist Planing Mills on Perth ave., recently. What started the fire is not known. The fire department soon had it under control. The loss is covered by insurance.

Toronto, Ont.—Willis K. Jackson, a wealthy lumber merchant of Buffalo, has purchased two townships in Northern Ontario from the Ontario Government for $98,364, at one dollar an acre. Acting upon a plan to secure private capital and private enterprise in the work of colonizing the unsettled portion of the province, the Government has entered into an agreement with Mr. Jackson whereby the Townships of Haggart and Kendry are sold on the understanding that the land will be immediately cleared, sawmills costing over $70,000 erected, and settlers brought into the district. Undoubtedly this is the most important step thus far in connection with the Government's colonization scheme. The purchaser must commence within 90 days from the date of the agreement and complete with reasonable despatch a permanent sawmill, planing mill, sash and door factory, all of which will cost something more than $70,000.

Fort George, B.C.—Another industry is about to start operation here in the form of a sash and door factory. The promoters are F. Wegley, R. A. Pooley, and S. Pooley, who will constitute the new firm to be known as the Fort George Sash and Door Factory.

Port Hope, Ont.—Fire recently damaged the planing mill of L. E. Hall and did considerable injury to the machinery. The cause of the fire is unknown. The loss amounts to $1,500, and is covered by insurance.

Pictou, N. S.—The plant of the Atlantic Milling Company was recently destroyed by fire. The total loss is about $28,000 and the insurance about $13,000. The concern which was incorporated two years ago, as a joint stock company, has been doing a large business and will rebuild at once on a bigger scale.

BUILDING NOTES.

Camrose, Alta.—Work on the foundations of a new $100,000 normal school for Camrose will be commenced this fall, according to Hon. J. R. Boyle, Minister of Education, who spent Wednesday here and made the announcement before he left.

Portage La Prairie, Man.—The Hart-Parr Company will erect a new warehouse to cost in the neighborhood of $5,000 in this city, and instructions have been given to their

architect, C. H. Mounsey to proceed with the plans and call for tenders at once. The building will be a solid brick structure, two storeys high, and will be situated on the corner of Gaddy and Victoria streets, the former site of the planing mill. The property was purchased three years ago by the company.

Portage la Prairie, Man.—The work of building the drier in connection with the new plant of the Portage Brick and Tile Company at the east end of the city is going on speedily, and in a short time the work will be completed and premises ready for operation.

Moose Jaw, Sask.—Building operations will start at once on the new city hall, the tender for which was awarded to Messrs. Navin Brothers for all but the heating and plumbing. The cost of the work is estimated at $25,900.

Regina, Sask.—F. Ryan and Company, boot and shoe manufacturers of Winnipeg, have decided to erect a five-storey building here and work will begin immediately.

Vancouver, B.C.—The contract for a three-storey reinforced concrete brick and stone-faced, 18-room school for Vancouver Board of School Trustees is about to be let. The school building will be one of the largest of its kind in Vancouver and will cost $150,000. Oil fuel will be used for heating throughout.

Vancouver, B.C.—Work has just been commenced on the eight-storey structure of the Y. M. C. A. here. It will occupy a space of 132 feet by 132 feet an dwill cost about $350,000.

Edmonton, Alta.—Plans are made and work will soon commence on the erection of a huge business block at the corner of McDougall and Rice streets. The building will be nine storeys high, and will contain 160 offices. Three elevators having a speed of 400 feet per minute will be installed. Over $500,000 is the estimated cost.

Montreal, Que.—A new military school is to be established at Dorval, on the island of Montreal, by the Dominion Government, 204 acres having been purchased at a cost of $180,000. Most of the area will be devoted to training officers of the local militia. Plans will shortly be drawn up, and it is expected that work will be started this fall, so that everything will be in readiness for training courses next spring.

Toronto, Ont.—The West End Y. M. C. A. building at the corner of College street and Ossington avenue is nearing completion and is expected to be finished by September next It is four storeys high and has about 125 feet frontage on both streets. Thirty-one distinct contractors are engaged on the building, which will cost slightly over $100,000.

Toronto, Ont.—The Home Life Association of Canada is going ahead with extensive and elaborate plans to add to their present buildings at the corners of Adelaide and Victoria streets. Nothing definite has been decided, but it is possible that a sixteen storey building will be erected.

Port Arthur, Ont.—It is reported that a Roman Catholic cathedral will be erected at the corner of Arthur and Algoma streets in the near future. As soon as specifications can be prepared, tenders will be called and work commenced as soon as possible thereafter.

Vancouver, B. C.—A girls' residential school is about to be commenced here. The school which is to bear the name of "Braemar" will be one of the finest of its kind in the province. There will be, as it were, two buildings—the school and the residence. Messrs. McLure and Fox are the contractors and according to their estimation the buildings will cost $115,000.

Vancouver, B. C.—A bank building, to cost approximately $100,000 will soon be erected at the corner of Carrall and Hastings streets for the Merchants Bank of Canada. It will be three storeys high, but will be designed to carry seven more floors.

Simcoe, Ont.—The York county engineers who act as consulting engineers for Simcoe, are now preparing designs for six new bridges to be built in that county this summer. One of these is to be of the concrete truss type, and will be located near the village of Nottawa, not far from Collingwood. The other five will be steel structures of expensive design.

Vancouver, B. C.—Work has started on the new St. Paul's Hospital. The building will be five storeys high and will be modern in every way. It will cost about $200,000, and will be ready by January next.

Toronto, Ont.—Authority has been given the Board of Control to purchase a site for the proposed detention house for the insane, to cost about $100,000. It is expected that work will be started soon on the erection of a building.

Winnipeg Man.—A permit has been taken out for the additional two storeys on the W.

PHONE MAIN 1615

AMERICAN MACHINISTS LIMITED
367 ST. JAMES STREET, MONTREAL

J. Boyd building. The total cost of the building will be $250,000.

Regina, Sask.—Negotiations are taking place between the Trade and Commerce Department and several Canadian and American manufacturers of elevators for the construction of the new Government terminal elevator at Regina. It is to cost two million dollars, and to hold three million bushels. While the main building will be constructed this season, it is not expected that the drying plant will be in use until next year. Tenders will be called for immediately.

Saskatoon, Sask.—A large block is about to be constructed here by Frank Cahill who has bought much property here. The size of the building is to be 135 feet by 130 feet and will be two stories high with provisions for an additional eight floors. The ground floor will be taken by stores, whilst the top will be used for offices. The cost is about $75,000.

Dunsmuir, B. C.—Among the several large buildings which Edward J. Ryan is about to erect are two buildings of very large proportions. One, an eight-storey apartment block which will cost $100,000, is to be built at the corner of Granville street and Twelfth avenue. The other building, at the corner of Dunsmuir and Seymour streets, will cost about $200,000. L. Melikoff is the owner.

Vancouver, B. C.—The chief losses occasioned by the recent big fire are:—Champion and White builders' supplies, $450,000; Canada Malleable Steel Range Company $75,000; Commercial cars in Motor Company's warehouse, $225,000; British Columbia Railway, $50,000; Tudhope Motor Company $30,000; and Palmer Investment Company, $75,000.

Saskatoon, Sask.—A block to be known as the Farnam block is about to be started here. The structure will be of solid brick and will be three storeys high. The cost of the building will be about $20,000.

THE EASTERN CAR CO.

Mr. Charles Cantley, assistant to the general manager of the Nova Scotia Steel & Coal Company, was in Montreal recently and reported that active preparations are afoot for the construction of the plant of the Eastern Car Company, which will go into the manufacture of steel cars. The plans for the building, which will cover about fourteen acres of ground, are well in hand, and Mr. Horace H. Lang, consulting engineer, who has planned many big American plants, is now on the ground. The site selected is close to the present Scotia plant at Trenton, a suburb of New Glasgow. Mr. Cantley reports that the recent additions to the Scotia plant both at Trenton and Sydney Mines are working splendidly and justifying the heavy outlay incidenal to the installation. Mr. Charles Cantley is a graduate of the Science Faculty of McGill, and a son of Mr. Thomas Cantley, General Manager of the Nova Scotia Steel & Coal Company. He was recently appointed assistant to the General Manager. Nova Scotia Steel is directly interested in the Eastern Car Company as it will supply all the raw material entering into construction.

THE RUSSELL MOTOR CO.

The Russell Motor Company has taken out a permit for a new building at its plant at Toronto Junction which is to be erected at a cost of $75,000. Work has already been commenced and operations will be rushed to a completion. The new structure will be a factory of four storeys, 170x120 feet in dimensions, being of re-inforced concrete with a maximum of light and equipped with every contrivance characterizing modern factories. The first floor will be devoted to a machine shop, the second an assembly for intricate parts, the third for rough parts and the fourth a finishing department. The new building will mean a considerable increase in the volume of the output of the firm, as also in the number of hands employed. About 1,200 are now engaged, and on the completion of the building, 150 additional will be required. The business of the firm continues to be brisk and the general outlook is very promising.

NATIONAL STEEL CAR CO.

Work on the new plant of the National Car Co. at Hamilton is being rushed, and it is expected that the company will be turning out cars early next year. The plant, which will have a capacity of 30 cars a day or about 9,000 cars a year, will be thoroughly up-to-date besides being well located on the water front with good shipping facilities. There is a good field in Canada for railroad equipment companies, the demands of Canadian railroads being more than existing manufacturers in this country can supply. The railroads are using about 25,000 cars a year. Duty on cars imported from the United States is 30 per cent. It is expected that the cost of buildings, machinery and miscellaneous contingencies will be about $650,000. The balance of the company's funds will be available for working capital. Capitalization is $3,000,000 preferred and a like amount of common stock.

CATALOGUES RECEIVED.

The Hisey-Wolf Machine Co., Cincinnati, Ohio, manufacturers of portable electric machine tools, have mailed us a copy of their latest catalogue, which makes very interesting reading. All kinds of portable electric drills, buffers and grinders are shown, not the least ingenious being a tool post grinder. This is a motor driven grinding wheel arranged to take the place of the ordinary tool post on the slide rest of a lathe. It can be used for grinding lathe centres, milling cutters, reamers, dies, rolls, etc., and also for internal grinding. The catalogue is attractively printed and contains much interesting matter.

The Independent Pneumatic Tool Co., Chicago, Ill., have forwarded several circulars descriptive of the various "THOR" tools manufactured by them. These include piston air drills and wood boring machines, pneumatic chipping, riveting, calking and beading hammers, etc., etc.

The Rockford Drilling Machine Co., Rockford, Ill., have issued an interesting booklet on jigging and tooling. The firm specializes in gang drills and this booklet illustrates the numerous advantages which such a drill has over a chucking lathe for many classes of work. It is well worth perusal.

The Fosidick Machine Tool Co., Cincinnati, Ohio, call attention to two circulars which they have recently issued describing their 30-inch and 36-inch National or simple type radial drills. These machines are of the company's latest pattern and have all up-to-date improvements.

The American Tool Works Co., Cincinnati, Ohio, have published a booklet bearing the title of "Accuracy Bulletin." In it are described and illustrated the methods taken for securing the high degree of accuracy in "American" machine tools.

John H. Hall & Sons, Ltd., Brantford, Ont., the well-known manufacturers of pipe lathes, nipple machines, roller pipe cutters and special machinery for tube mills have favored us with a copy of a handsome new catalogue which they have just published. It is of the loose leaf variety, excellently printed on faced paper and gives very full particulars of the various high-grade pipe machines manufactured by this progressive firm.

The Kelly Redner Co., Cleveland, Ohio, have issued their 1912 catalogue and net price list. This shows all types of these reamers, which are of the adjustable type with blades of high-speed steel. These reamers, it is claimed, give so accurate a finish that subsequent grinding is never necessary.

The Curtis & Curtis Co., Bridgeport, Conn., have sent us their latest catalogue dealing with the Forbes patent pipe cutting and threading machinery, for hand, belt or electric power. These machines have several features of interest all of which are fully described in the catalogue.

Henry Disston & Sons, Philadephia, Pa., and Toronto, Ont., will be glad to send to parties interested their handy pocket catalog of wood and metal-working saws, all of which are fully guaranteed.

The British Pacific Supply Co., Victoria, B.C., have mailed us an illustrated pamphlet describing the new graphite bearing material which they have recently put on the market. This preparation is known as GRAPHITOL and consists of a fine, dry powder, which, when required for use, is mixed with a prepared liquid into a stiff paste and, without the application of heat, is put into place in the bearing, then formed or moulded, and allowed to set, which it does in from eight to twelve hours. It is claimed that a bearing of great strength is thus formed, in which graphite is the principal ingredient., thus rendering the bearing largely self-lubricating.

NOTICE

TAKE NOTICE that the Stanyon Metallic Furniture Co., Limited, of the City of Toronto, duly manufactured the movable grate covered by Canadian Patent No. 101,907, and that the Bennet & Wright Co., Limited, of the same city, duly manufactured the hot water heater covered by Canadian Patent No. 107,120, prior to the period called for by the Patent Act, and the said firms are prepared to fill any further orders for the two above inventions at a reasonable price. Ridout & Maybee, Solicitors for Anders B. Reck.

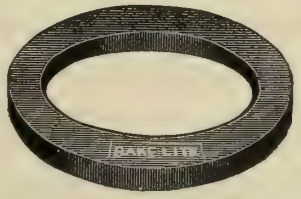
GALT FOUNDRY CO. GALT, ONT.

High Grade Malleable Castings
OF ALL SIZES AND KINDS
Galt Malleable Iron Co., Limited - - Galt, Ontario

These are the telling points about

Bakelite

Valve Discs



They will not leak under high temperature, excessive pressure or when used in acids or other special liquids. Neither cold water, dry or superheated steam has the least effect upon them. **BAKELITE** Discs are a gas-tight fit.

BAKELITE is a successful substitute for expensive metal. Its structure is fibrous, giving strength and hardness. It can be reground and refaced, always retaining a uniform surface. It cannot be injured, except by accident or friction. Remember Bakelite **PUMP VALVES** do not warm with changes of temperature.

Order your valves fitted with Bakelite Valve Discs and stop that perpetual annoyance and expense caused by leaking valves. Depend upon it, Bakelite Valve Discs will not leak.

EFFICIENCY

Is the main consideration in your Power Plant. There is only one way to obtain it, and that is:—

BUY THE BEST

equipment you possibly can and DEVELOP YOUR OWN POWER. By so doing you save money and in addition you have a steady service all the time. The Power is not off just when you need it the worst. Such service means EFFICIENCY.

Illustration shows H. D. Goldie Corliss & Vertical High Speed recently installed by us.

The Best Quality of Material and Workmanship

are used in the construction of Goldie & McCulloch Engines, Boilers, etc. There is nothing better made.

Any Machines Or Tools Damaged Or Broken?

Many firms throw broken machinery or tools intc the scrap heap because they consider them worthless. Send the broken parts to us.

We Can Make Them As Good As New

By Our Process Of

AUTOGENOUS WELDING

By this system metals are united without soldering or compression. The welded part is practically as strong, if not stronger than the rest of the metal. We make repairs promptly, whereas you would lose much time in waiting for a new tool or part of machine. Do not confuse with brazing, which is done at a much lower temperature.

WELDING WILL SOLVE SOME OF YOUR DIFFICULT SHOP PROBLEMS ALSO. WE UNDERTAKE THE MANUFACTURE OF SPECIAL ARTICLES IN QUANTITIES, BY WELDING.

No work too small or too large for our capacity.

We employ only the highest skilled French experts and use only the best equipment.

Prices low in comparison with the **quality** of our work.

Complete welding and cutting plants supplied, installed and put in operation for customers.

It will certainly pay you to consult us.

"MORSE" DRILLS

WITH OIL HOLES THROUGH SOLID METAL

for conveying lubricants or air to the points.
These drills are the only tools of their kind made in this way.
No tubing to catch in the work and rip out.
Are much stronger than oil tube drills. They have the same clearance that other "MORSE" DRILLS do, which is a great advantage.
Air is sometimes used to blow out the chips and to keep the drill cool. Fully described and illustrated in a "MORSE" Catalogue.

"Morse" Drills and Tools are handled by:—Rice Lewis & Son, Limited, Toronto; Aikenhead Hardware, Limited, Toronto; Frothingham & Workman, Montreal; Mechanics Supply Co., Quebec.

Noon Couplers

(Copy)

Noon Universal Coupler Co., Limited, Toronto, Sept 5th, 1911.
Toronto, Ont.

Dear Sirs,—We have been using the Noon Universal Hose Coupler since April 1st, and we are pleased to state that it is the most efficient coupling we have ever used and gives perfect satisfaction.
We were the first people to use these couplers

Yours truly, TORONTO IRON WORKS, LTD.,
J. H. Malone, Superintendent.

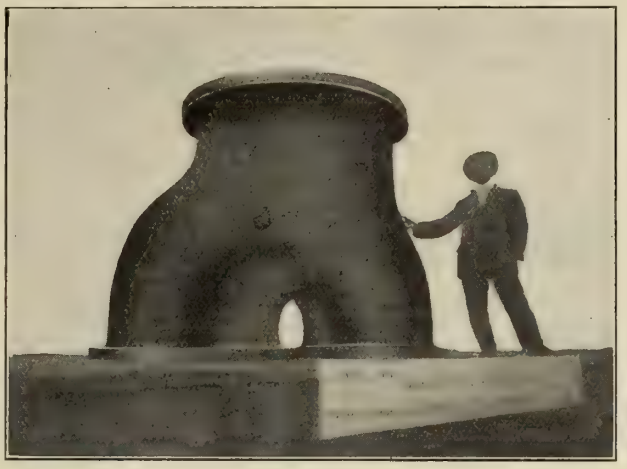
STEEL CASTINGS

Our castings are as perfect and efficient as castings can be, yet they can be procured at a price that will ensure economy.

Let us submit you estimates before placing your next order. Write to-day.



Casting for a 10,500 H.P. Water Wheel.

We make New Process Converter Steel Castings, annealed and unannealed.

We also make Chrome Manganese Nickel Steel Castings.

Made in any size from ¼ lb. to 3000 lbs. and **guaranteed right.**

Joliette Steel and Iron Foundry, Limited

Head Office and Foundry - - - JOLIETTE, P.Q.

STEEL

Sheets and plates – any width up to 50 inches, any thickness up to one inch.

Merchant bars, shafting and heavy forging of all kinds.

PIG IRON FOR FOUNDRY USE.

UNSURPASSED EVAPORATION HIGHEST IN CARBON **COAL** LOWEST IN ASH BEST ALL ROUND STEAM COAL.

IN
BRASS—BRONZE—ALUMINUM

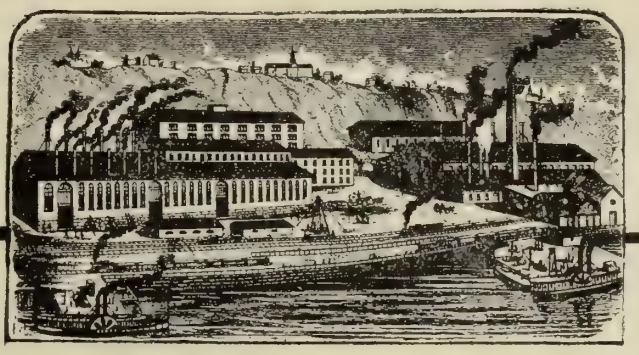
The New Booklet, describing over twenty Alloys, is in press. It is of value to Engineers and to all users of brass and bronze.

LUMEN BEARING COMPANY, TORONTO

DIE CASTINGS, in Babbitt Metals, Lumen and Special White Alloys, to an accuracy of 0″.001.

Write for the Booklets. They are INTERESTING.

MARINE ENGINES and PUMPS. SHOE MACHINERY A Specialty



BRASS and IRON CASTINGS. BOILERS and REPAIRS.

That we have exceptional facilities at our disposal for the manufacture of all kinds of Machinery—in addition to our business as Brass and Iron Founders, General Contractors and Shoe Machinery Engineers—has been amply proved this year. In the short space of five months, we built and installed all the Engines and Boilers of the new sister steamers "Levis" and "Lauzon," whose trial trips were a complete success. We make a specialty of all kinds of Marine Engine Work, and shall be glad to quote for first-rate products only.

SHOE MACHINERY. Manufacturers of "Non-Royalty" Machines, Metallic and Goodyear, "Fortuna" Skivers, and "Climax" Presses, Sand-papering, Lasting and Loose Studding Machines.

Wire of every description for Slugger and Standard Screw Machines.

The Canadian General & Shoe Machinery Company, Ltd.

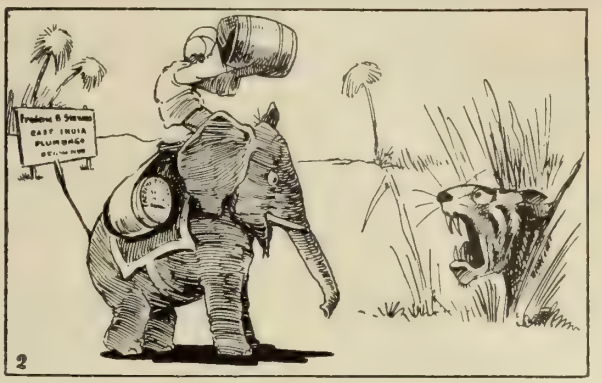
Dixon Crucibles

EVERY crucible made by DIXON since 1827 has been made with the one idea of giving reliable service.

¶ In doing this nothing has been so helpful as our experience and our study of actual foundry conditions. ¶ In the purchase of raw material, in mixing it correctly, in spinning up the crucible, wherever there has been any question our experience has been called upon to give the final answer.

¶ Write for our booklet No. 223-A on the care and use of crucibles.

Joseph Dixon Crucible Company
Jersey City, N. J.



On the Defensive!

There are times when the Foundryman is on the defensive.

It is when the tiger of competition is too self-assertive.

In the reduction of costs a new profit is created.

Stevens' Pure Plumbago reduces cost

One New York Foundryman writes:—

"Your Lead gives me the best peeled castings I have had for a long time, and the color is right, too."

That means that this Lead does the work expected in the Foundry instead of leaving it for the scratch-room or the chipping room to finish.

That means labor saving and cost saving.

Each shipment has its return ticket—it may be returned and freight paid by me both ways when not satisfactory.

The entire risk is on me!

Its use squelches all tiger danger.

I manufacture the entire line of **Foundry Facings and Foundry Supplies**, and the quality stamp impresses them all.

FREDERIC B. STEVENS

DESCRIPTION

Length over all, 5 feet 6 inches.
Height to centre of shaft, 38 inches.
Weight, 375 lbs.
Length from end of spindles to tight collar, 7 inches.
Length of Spindles, 30 inches.
Diameter of Spindles, 1⅜ inches.
Diameter of Spindles for wheel, 1¼ inches.
Tight pulleys, 5¼ inches.
Loose pulleys, 5 inches.
Crucible steel spindles.
Bearings extra long and babbitted with Phoenix babbit metal.
All bearings carefully scraped.
With or without Shifter.
Slight extra changes to meet special requirements without extra charge.
Fitted with Compression Oil Cups.
Pulleys turned inside and out and carefully balanced.
Strong and durable and made for extra hard usage.
A strictly high-grade machine and fully guaranteed in every respect.

PROMPT SHIPMENT GUARANTEED.

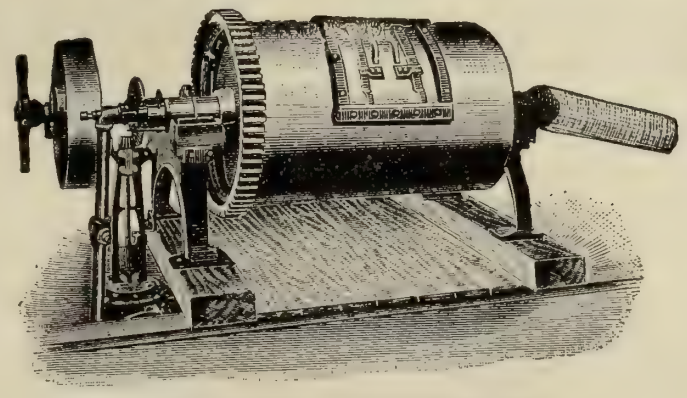
A GOLD MINE

SAVE YOUR IRON



SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

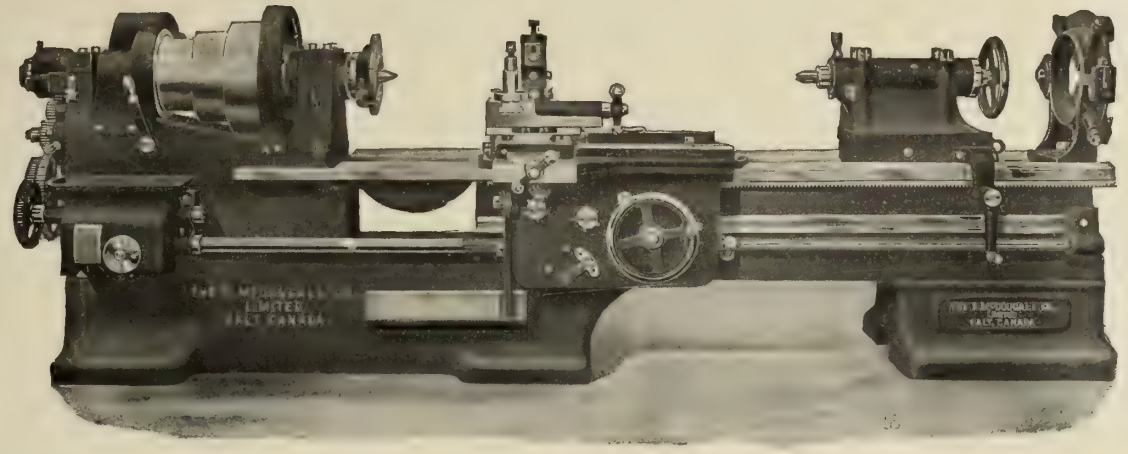
Here is a Solid, Safe and Adaptable Lathe Equipment for Your Factory



CANADIAN factories must provide equipment under exceptional conditions of their market. It is growing. Their shop output must be gotten out under constantly increasing pressure.

Ordinary lathe equipment will not meet this condition, if wise factory economics are to be observed.

With this condition looming up in the business horizon just ahead, the New McDougall Lath represents the extraordinary lathe equipment that should be bought now to combat successfully the growth of output that is hanging over every shop in the Dominion.

In a word, we have put reserve strength into every feature of the McDougall Gap Lathe. We fit it for to-morrow's need, by foresight in the designing to-day.

To-day it is two lathes in one. The gap is filled by our removable bridge. The gap is supported by the extension footing. For all practical purposes, it is a combined gap and standard-bed lathe in one, because the extended footing under the gap makes it as solid in the bed as the one-purpose lathe. It is now a flat-bed tool—remove the bridge and it is a gap lathe, doing work far cleaner than the average gap machine.

Note the solidity of the head construction and the large wide bearings. These bearings are protected in every way against deterioration by grit-proof protective devices and automatic oiling; The bearing surface is in them to stand speeding up the cut or to increase its width. These typical service features of design provide for low deterioration to-day—for big output at high speed to-morrow.

The bed, which cannot be seen in the illustration, is stiffened to correspond. Every device of webbing and bracing is used to prevent springing. This means quality of work now as well as ability to handle work under high speed demands and much heavier stresses to-morrow.

The carriage corresponds in solidity and bearing area to the strength of bed, and the wide apron greatly increases the evenness of travel and accuracy of manipulation with very low deterioration.

The safety interlocking device on the tool feed (to thousandths both ways) and the quick change features of tailstock, give this machine full adaptability and elasticity in making changes of work, as well as in actually turning work out.

Note the double usefulness of this McDougall Gap Lathe, its flexibility as a part of your equipment, its reserve strength and capacity for future needs, and its low rate of deterioration. It is the one equipment for your factory that there is undoubted wisdom in buying. Ask us for details of gap and length of bed. Write now.

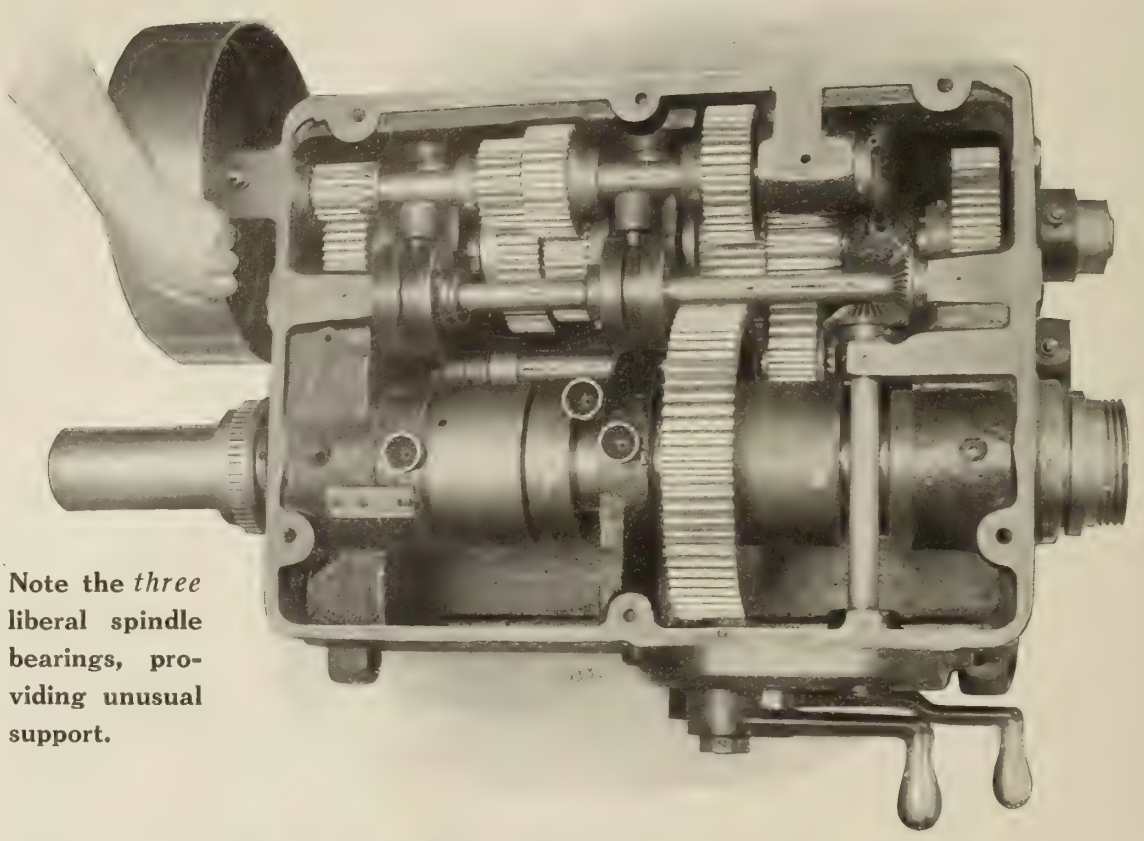
A Good Head Means Power



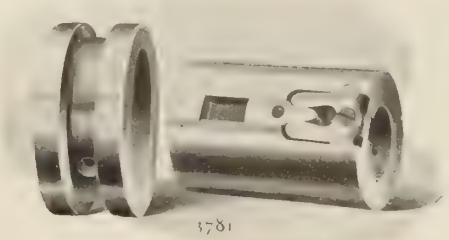
Note the *three* liberal spindle bearings, providing unusual support.

The P. & W. Turntable Lathe

is provided with a remarkably well built head. A few distinctive features are as follows.

1. Head is oil tight, permitting gears to run in an oil bath.

2. All gears and clutches are accessible by simply lifting off the head cover.



3781

Expanding ring clutches used in headstock

3. All gears are of coarse pitch and have a wide face.

4. All bearings are provided with independent lubrication.

5. Boxes are of bronze, are accessible and have easy adjustment for wear.

6. Spindle is located centrally on the ways, bringing work close to the operator.

7. Unequalled clutches of the expanding ring type are provided. They are easily and quickly engaged, and afford a very powerful grip. They are accessible, easily adjusted and their durability is unquestioned.

8. Eight spindle speeds covering a wide range are available. They may be changed while the machine is running and are within easy reach of the operator, while watching his work.

Write for full descriptive catalog "Turntable Lathe."

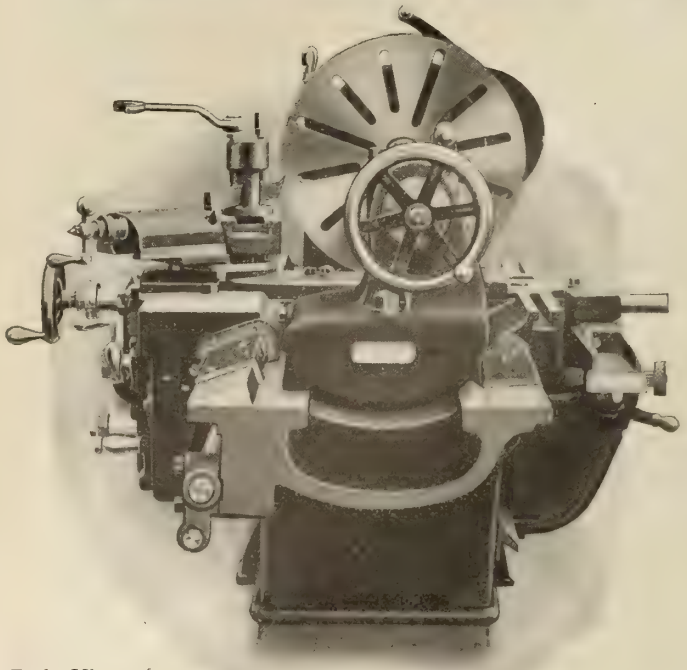
LeBlond Heavy Duty Lathes



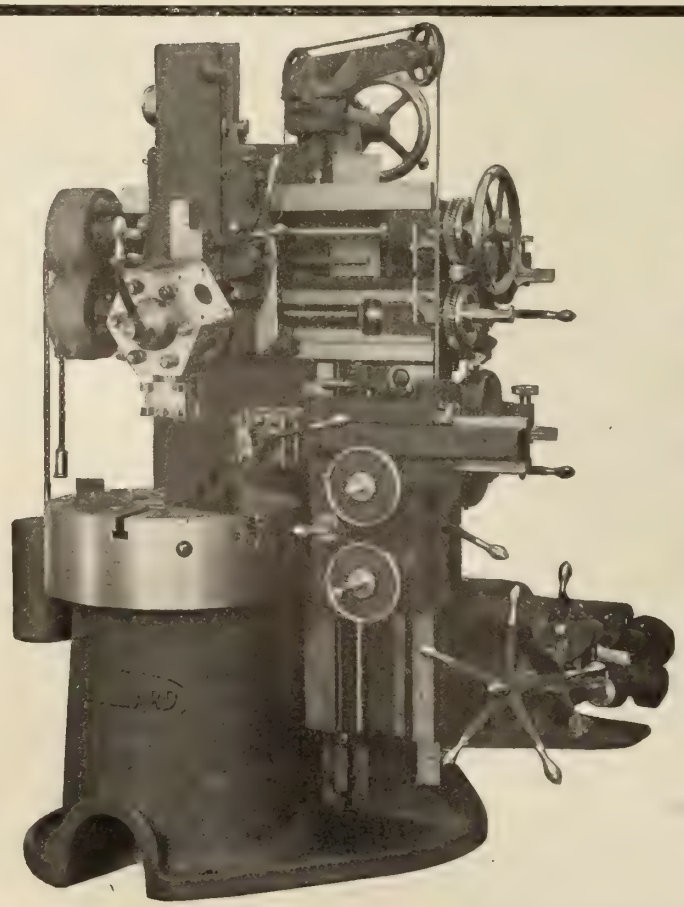
End View of H. D. Lathe.

Are especially adapted to the heaviest kind of manufacturing and modern high speed production. They are not the regular type of lathe dubbed heavy duty, but machines designed and built for just this kind of work.

WRITE FOR DETAILS.

The R. K. LeBlond Machine Tool Co., Cincinnati, Ohio

Canadian Agents—GENERAL SUPPLY CO , Ottawa, Toronto and Winnipeg.



You Pay for the Bullard Vertical Turret Lathe Whether You Buy it or Not

and the longer you wait, the more you pay.

IF YOU ARE NOT USING THIS MACHINE YOU PAY FOR IT, NEVERTHELESS, WITH THE MONEY LOST BY YOUR PRESENT METHODS OF PRODUCTION OF ALL FACE PLATE WORK WITHIN THE RANGE OF THE VERTICAL TURRET LATHE.

This loss is caused principally by wasted time.

The fundamental principle of the Vertical Turret Lathe is the "**elimination of wasted time.**"

Time between cuts is reduced by centralized control of the operation of the whole machine, as well as by rapid power traverse of all parts.

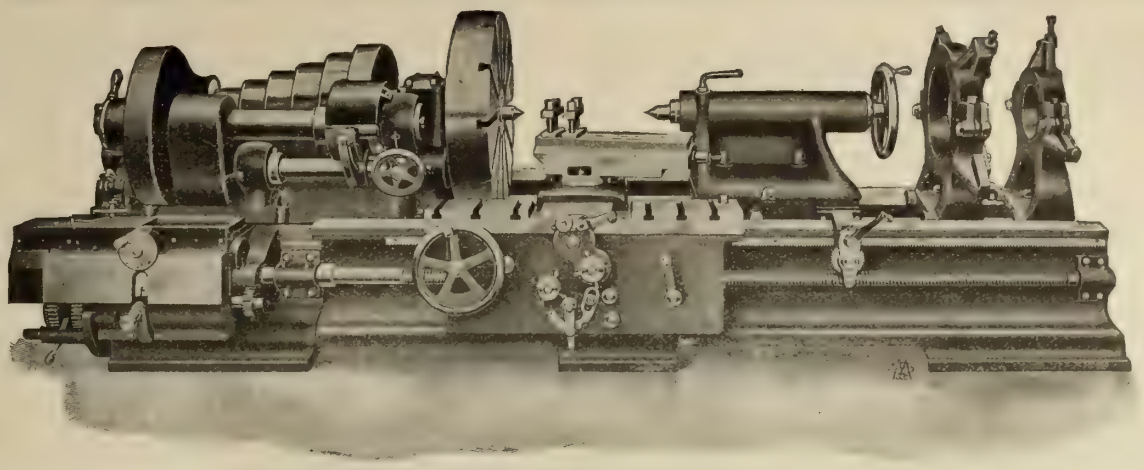
With both a Turret and a Side head, machining of several surfaces at once is possible—**MULTI-CUTTING.** And all the tools needed for a series of operations are held in instant readiness.

In all, every possible moment of the machine's and the operator's time is utilized and made efficient.

Ask for Treatise on Face Plate Work C-15.

THE BULLARD MACHINE TOOL CO.

BRIDGEPORT, CONN., U.S.A.



42-inch TRIPLE GEARED ENGINE LATHE

Instantaneous Change Gear Device, all changes for feeds and screw cutting made without removing a gear and without duplication.
Power Angular Feed to Compound rest of twelve inch travel.
Double Plate Apron prevents all overhang and straining of studs and pinions.
Tail Stock is provided with pawl to engage rack cast in bed.

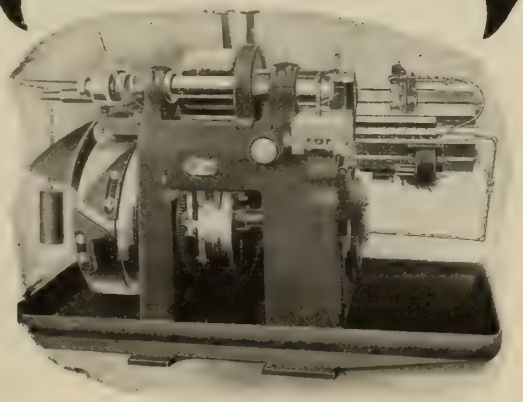
(Maximum belt pull transmitted to the cutting tool.)

THE BOYE & EMMES MACHINE TOOL COMPANY

Successors to SCHUMACHER & BOYE

Engine Lathes. **Cincinnati, Ohio, U.S.A.**

Gridley Automatic Turret Lathe



"GRIDLEY" SINGLE SPINDLE

Handles Work Of Greater Length And Of More Complex Character Than Any Other Machine Of This Kind

Every cut that the "Gridley" makes is accurate, smooth and perfectly uniform from start to finish.

The "**Gridley**" is **simple.** One operator can run several machines at once, and can use tools tandem, thereby increasing output.

The "Gridley" is the only automatic that gets away from the old box tools and uses extra strong tools on the slide.

Give the "Gridley" a trial. If not as we claim ship it back at our expense.

We also manufacture the **Gridley Multiple Spindle Automatic.**

Write to-day for illustrated catalogue.

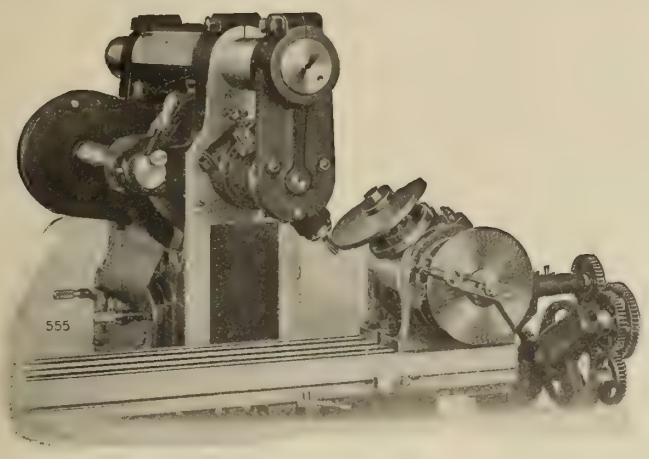
Milling Screw Machine Cams

The Cincinnati Way



This is one of the jobs that generally puzzle the toolmaker who has to do it right. The difficulty is that the great variety of cams used all require exact leads, most of which cannot be produced by any practical combination of changed gears.

On a Cincinnati you gear the Miller for one of the shorter leads. Then by setting the Dividing Head and the Vertical attachment at an angle you get a mathematical relation between the forward movement of the table, the revolution of the Dividing Head spindle, and the angle to which it is set, which produces the exact lead required.

We have figured out all the settings for you for leads, from .6 inch to 6 inch advancing by .001 inch.

You can have these tables for the asking if you are using a MODERN CINCINNATI UNIVERSAL.

The Cincinnati Milling Machine Company

CINCINNATI, OHIO, U.S.A.

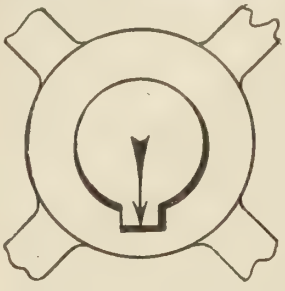
Our Broaching Machine is for cutting keyways in holes; and broaching square, hexagon, or other shaped holes, being the most practical and rapid tool for this work.

Will cut a ¾" Keyway in 1 minute.



KEYWAYS AND SQUARE HOLES BROACHED IN A MINUTE.

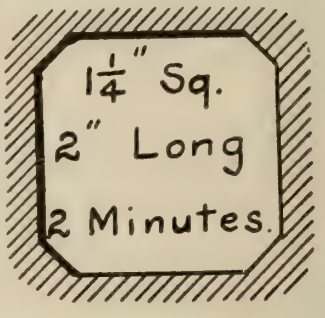
Square, Hexagon or any shape holes, Keyways, Spiral Grooves or any internal work can be done in less than 5 minutes on this machine.

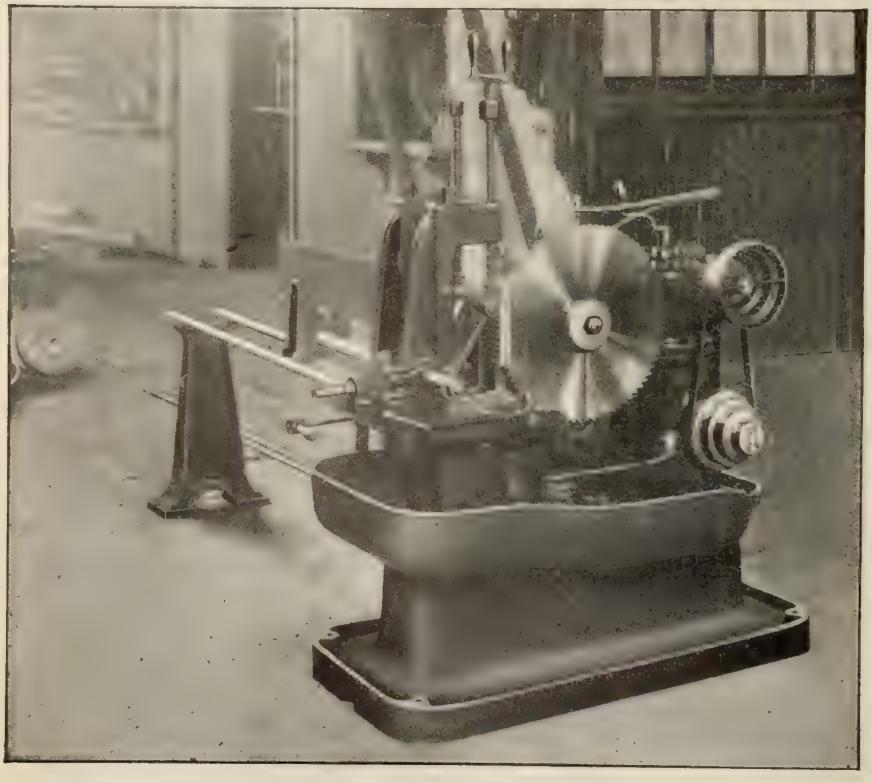
Write us and give description of your work.

The J. N. Lapointe Co.

MARLBORO, - - - - - MASS.

Will broach any size square hole.





3240 Pieces Flat Steel 1-2x1 in. cut per 9-Hour Day with No. 4-B, 6 in. Size

Cochrane-Bly Cold Saw

Cutting 12 Bars at once.

All pieces accurate within .002 inch.

The rapidity, accuracy and economy of Cochrane-Bly Cold Saws is strikingly illustrated by such work as this. The five sizes cover all machine shop requirements, reducing the CUTTING-OFF problem to a matter of selecting the right size for the work. Our experience in this line is freely at your service; we can help you do this work faster, with greater exactness, and at a cost saving worth while. We will be glad to tell you how it can be done.

COLD SAWS—Five sizes.

AUTOMATIC SAW SHARPENERS—Two sizes.

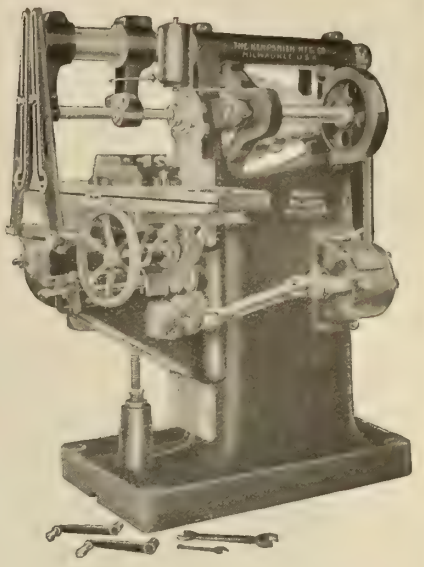
DIE FILING MACHINES—Two sizes.

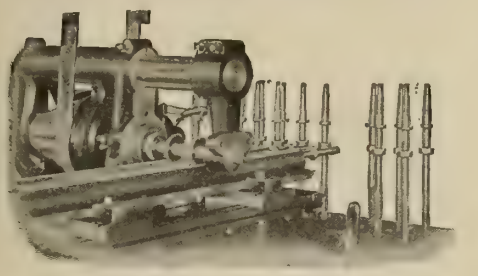
COCHRANE-BLY COMPANY, ROCHESTER, N.Y. U.S.A.

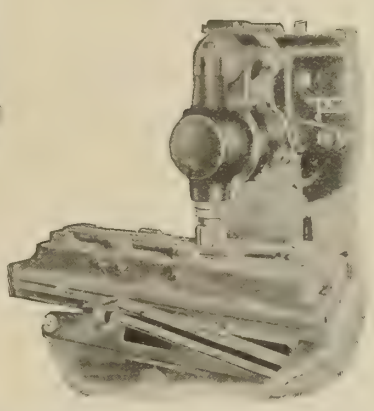
KEMPSMITH

No. 2-A Plain Miller

with its 36 *inch* Automatic table feed, extensive table surface, extremely rapid return, and concentrated operation, is an ideal manufacturing machine







for keyway cutting, and long light cuts, and in duplicate manufacturing, in which quantities of small parts are set for one travel of the cutter, for cuts which are long, yet do not require a big powerful machine in proportion.

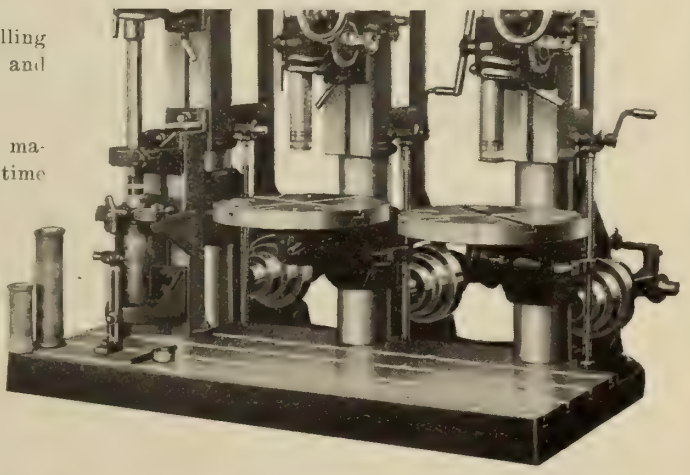
The KEMPSMITH MFG. COMPANY, Milwaukee, Wis.

Rockford Drilling Machines

Are Quantity and Quality Producers at Low Labor Costs

THE ROCKFORD DRILLING MACHINE Co · ROCKFORD · ILL., U.S.A.

3 SPINDLE 31 in. GANG DRILL



And besides, they are more than mere boring and drilling machines. They are machines of versatility, elasticity, and practical economy in manufacturing equipment.

The secret lies in the proper jigging and tooling of the machine; gauging the number of spindles per operator to the time required for the longest operation, and the loading and unloading of pieces.

Every second spent by an operator hanging on to a lever or waiting for the power feed to run through the cut is a second wasted, and sufficient spindles should be employed per operator to keep his time fully occupied.

Write for our booklet, "Tooling and Jigging." It is the only book of the kind ever issued.

Rockford Drilling Machine Company

MOST POWERFUL MILLING MACHINE

(Knee Type)

GARVIN No. 22 Plain Milling Machine, Compound-Geared. Use Code, "Aperient."

The machine shown is the most powerful Knee Type Milling Machine manufactured by us, having Compound Back Gearing whose ratio is 10 to 1, through steel gears. It will transmit 10 horsepower to 14 inch cutters running 20 revolutions on steel castings. The machine has a wide faced pulley of 11 inches in diameter, running loose on the spindle. The power is taken from the countershaft by a 6-inch double belt to this pulley and double-backed-geared back to the spindle. The machine has an arbor 2 inches in diameter, solid, with spindle, thus avoiding a lot of arbor troubles.

DIMENSIONS

Length of automatic feed of table	28 in.
Dimensions inside of oil pockets	43½x9 in.
Vertical adjustment	15½ in.
In and out adjustment	7 in.
Crated weight	3250 lbs.

"Hendey" Centering Machine

Made to meet the demands of those who want a machine that will centre within reasonable limits of accuracy, and amply proportioned in spindle bearings, etc., to withstand wear and tear.

Head and Spindle Construction. The head is rigidly clamped to the bed, giving permanent alignment of spindle. Spindle is large in diameter with ample bearings, front journal being made taper after the well known pattern of the Hendey lathe head. Spindle carries draw-in attachment with watch tool chuck for accurately and conveniently holding combination centre drill and reamer. Thrust taken by ball bearing. Back locking pin working in flange of pulley is provided for use when necessary to remove or replace centre drill.

Jaws of Vise and supporting block are hardened and ground.

Alignment of Spindle with Jaws. Jaws are aligned from spindle by proof bar carried in spindle. This care in alignment is exercised in order to enable machine to accurately centre stock for finishing purposes after coming from turret lathe or screw machine.

Relative Movement of Vise and Block is maintained by means of the connecting rod and spur geared drive at back of machine, controlled from the one ball handle at front of vise. This means that, no matter what the diameter of the bar may be within the limits of the machine, it will **always be supported in a horizontal position,** there being no hand adjustment and "eye-alignment" necessary for back support.

Inclined Surface of Bed, sloping away from operator, tends to direct the chips into the pan, rather than have them accumulate around the head, necessitating frequent cleanings when it is desired to shift vise carriage.

Saddles are gibbed and fitted to bed, and provided with binding handles for ready clamping in position.

Heavy Parallel Bars, running the length of machine, serve the two-fold purpose of a rack for carrying stock to be centered, and, in connection with the inclined bed, prevent it from being bruised and banged through common use of bed as temporary support for the stock.

Capacity of Machine is from 5-16 to 4 inches, inclusive.

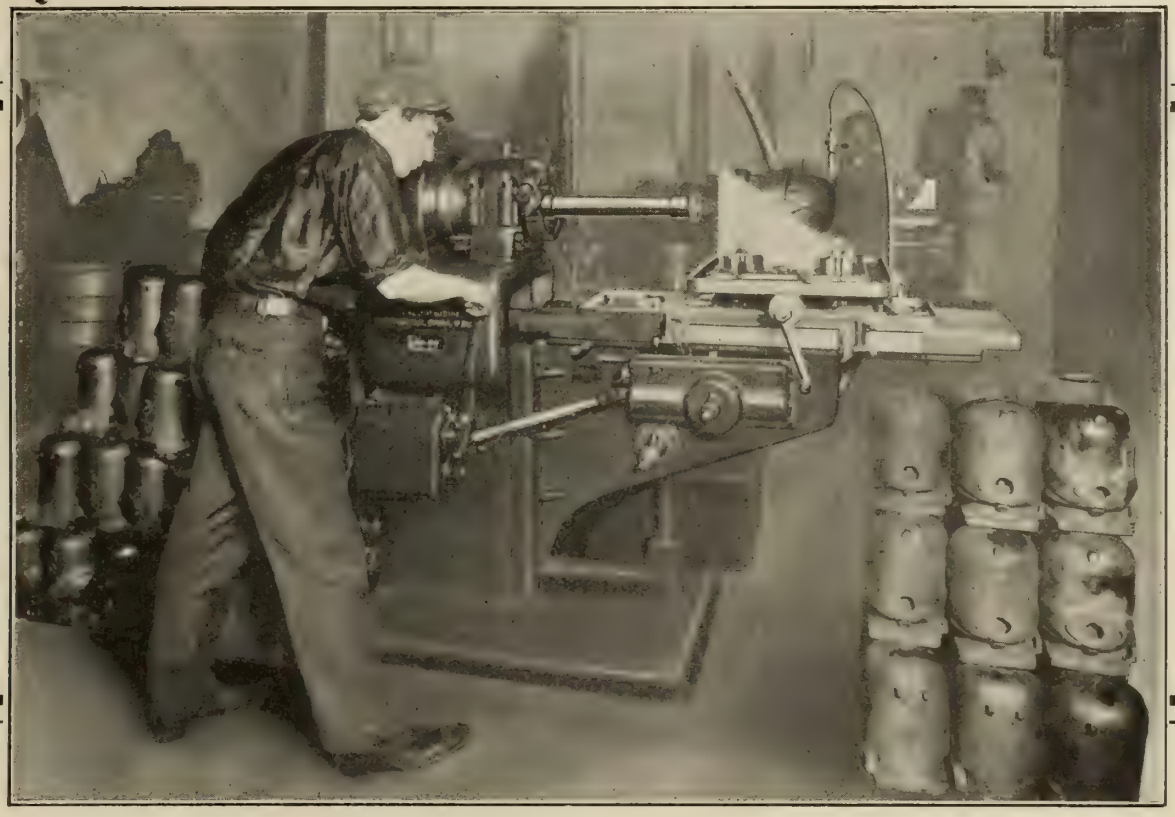
"Lapping in by hand."

HERE'S FOOD FOR THOUGHT

WASTED ENERGY **LOW EFFICIENCY**

Some shops are still "lapping in" gas engine cylinders by hand, as the above cut shows, and are doing a lot of hard work to accomplish something that can be done better and easier another way, as shown in the following cut.



This **one** man with the use of a Heald Cylinder Grinding Machine has obtained an output per day that it would require **several** men to equal, if they used the Reaming and Lapping method, and has produced **more accurate** and **better finished** holes than it would have been possible to obtain in the other way. How and why is explained in our booklet on "Cylinder Grinding." Copies sent free on request.

Detroit Twist Drills

Trade Mark

drilling operations —from which you profit

You have the *machine*, the *man* and the *material* to consider.

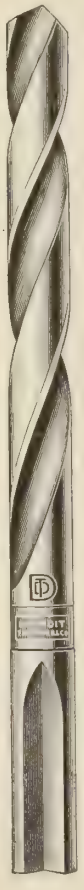
One operation involves all three. There's *cost* in every one.

The *profit* you receive from their combined output is not greater than that permitted by one small point.

The machine can't *cut*, the man can only *direct*, the material constantly *resists!*

It's the *contact between* your machine and the material that determines your profit. *This small tool* does the work.

The *efficiency* of your drilling operations depends upon your *drill.*



"Detroit Twist Drills"

—make these a source of profit to you. They *increase output* on the machines. They speed the *productiveness* of the men.

Consider the two *basic* reasons:

1. They cut the *most metal* with the *least* regrinding.

   Such increased capacity for *continuous* producing service is made possible in Detroit Drills by the *steel* from which they are made and by the *treatment* this steel receives. Chemical analysis insures a rigid constancy in the steel we approve. Heat-treatment —that 26 years *specializing* in the art has proved best to us— brings out the *very utmost* of strength and stand-up cutting powers in our finished drills.

2. They run *true* and cut *fast.*

   After each operation every *Detroit* Drill is inspected to see that it is progressing to specifications. As a result *every* drill we finish is a perfect one—to one two-thousandth of an inch! *Equal* lips, *central* web, *alignment* from tip to shank—make them a constant-stimulus-to-more-work to the man operating them.

You can make a profit in *machine time*, *labor* and in the year's *drill* cost—by a test this week in your own plant. A small lot of these drills will prove *your economy* in them—order from any Dealer in the country.

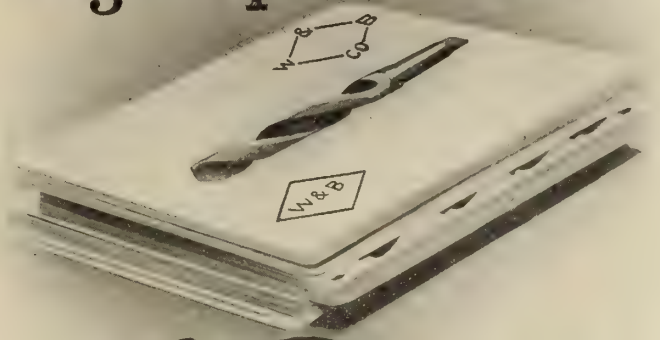
"DIAMOND" High Speed Drills



Are Trumps in the Drilling Game

The same claims to superiority are set up for every high-speed drill on the market. "Uniform Quality," "Great Cutting Capacity," "Careful Workmanship," and similar expressions have become stock phrases—plentifully sprinkled through every drill advertisement and through every salesman's talk. No wonder the buyer is often in doubt.

According to Hoyle, "When in doubt, play trumps"—and in the drilling game "Diamond" High Speed Drills **are** trumps. To use them once is to put an end to doubt—you'll play trumps every hand—never lose a trick—and quit 'way ahead of the game.

We can furnish Diamond High Speed Drills in all sizes—straight or taper shank.

Tools of Quality Bear These Marks

Business economy is only another term for profit—

Expensive, old-fashioned methods cannot compete with modern efficiency. You must make your profit through your savings in the cost of conducting business.

What about your cylindrical work finishing and sizing cost? Done on a lathe is profit wasted. This is an accepted fact. Time was, when finishing on a grinder was an experiment. It is now an accepted economy.

May we have the opportunity of proving the economies that the Bath Universal would effect in your business?

Arranged for Cylindrical Grinding.

GARDNER Vertical Spindle DISC GRINDER

This is the largest Disc Grinder, of any type or make, on the market. The disc wheel is 53 inches in diameter and is driven by bevel gears within the base of the machine. These gears run in oil bath and are completely shielded from any dust or dirt. A dust chamber lies under outside edge of disc wheel and connection is made in rear for attaching exhaust system.

A special pneumatic press is furnished for cementing new discs to wheel.

We also make our No. 24 machine with direct motor drive.

Simply place the pieces to be finished on the revolving Abrasive Disc and leave till finished. A number of pieces, according to size, can be ground at once. Operated by unskilled labor.

Scores of our No. 24 machines are in daily use. We will tell you where you can see one in operation.

Ask for free folder "Vertical Spindle Disc Grinding."

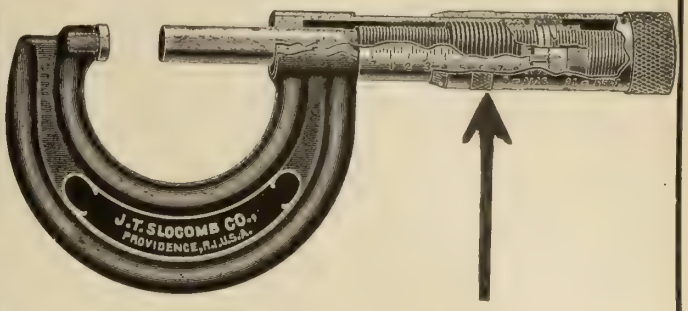
INVESTIGATE—IT WILL PAY YOU

The Lees-Bradner Co.

CLEVELAND, OHIO, U.S.A.



This Bearing is 7/8 in. long

Examine the micrometer you are using and see what length of bearing there is for the screw to run in. If it's 7/8 inch long it's a Slocomb, but if it is less than that then remember the next time you buy a micrometer that the long bearing means a longer life to the tool, and that the bearing in Slocomb Micrometers is 7/8 inch long.

Then notice the diameter of the screw. Slocomb screws are .270 inch diameter, while most others are .250 inch. If you are really interested we can tell you of several other features that are worth knowing about Slocomb Tools, and why they are "The Longest Lived Micrometers That Can Be Bought."

Our Combined Drills and Countersinks are made of Semi-High Speed Steel, and will do a vast amount more work than a regular carbon steel centre drill. We have paid particular attention to the shape and grinding of the tool so that it will produce the best results.

High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

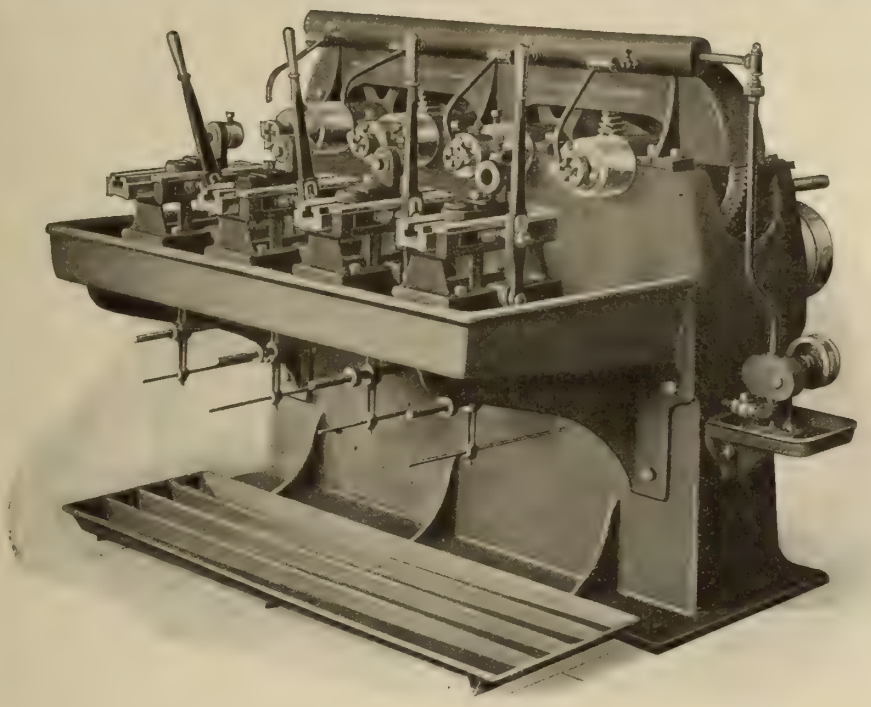
HERMANN BOKER & COMPANY

332 ST. JAMES ST., MONTREAL

Probably You Would Not Consider A Bolt Cutter Accurate Enough To Thread Cap And Set Screws,



yet many of the leading manufacturers in this line who have established a reputation for the accuracy of their product are using "**W. & P.**" **Threaders** almost exclusively for threading, after blanking on other machines, and we do not sacrifice capacity for accuracy either—the 4-spindle machine has a capacity of 9000-⅝ in. threads, 1½ in. long, per day of 10 hours (other sizes in proportion)

We would be pleased to send our complete new catalogue describing this and other sizes of Bolt Pointing, Threading and Special Tapping Machines on application.

The Webster & Perks Tool Co.

"Beaver" Adjustable Die Stock

Has Become Indispensable in Many Shops

because it is a stock of rare quality and efficiency which makes every inconvenient corner accessible.

Because it works so easily that it can be operated by a child.

Because each die stock contains one set of dies which can be easily adjusted so as to cut four different threads, eliminating the buying of three die sets, thus reducing much keep-up expense.

Let us send our quotations on power machines, any size from ⅛ in. to 12 in. Motor, Belt, Gasoline or Steam Driven.

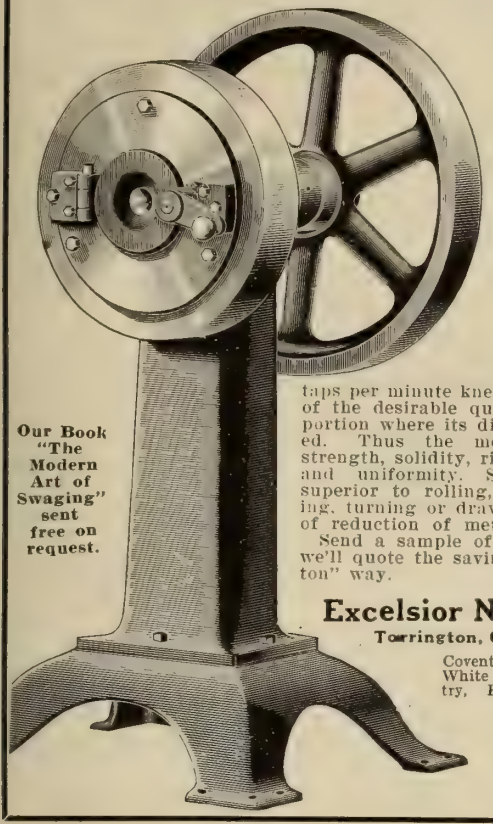
Universal Reversible Jaw Chuck

REDUCE METAL
WITHOUT WEAKENING IT



Our Book "The Modern Art of Swaging" sent free on request.

Swage The Dayton Way

The Dayton Swaging Machine does not sacrifice one particle of strength of the metal being reduced. From 2,000 to 6,000 taps per minute knead or squeeze all of the desirable quantities into the portion where its diameter is reduced. Thus the metal has added strength, solidity, rigidity, elasticity and uniformity. Swaging is far superior to rolling, grinding, milling, turning or drawing as a means of reduction of metal.

Send a sample of your work and we'll quote the saving by the "Layton" way.

Excelsior Needle Co.
Torrington, Conn., U.S.A.

THIS TEST REVEALS THE HIDDEN WEAKNESS IN ROOFINGS

All ready roofings—except J-M Asbestos (stone) Roofings—are made of so called felt composed of animal or vegetable fibres. When these fibres were growing, they lived upon the ground or animal from whence they came, and received their life therefrom. So every fibre of this nature is hollow, like a straw.

These felts are water-proofed with coal tar, asphalt and oil, or other volatile compositions which quickly evaporate when the sun reaches them. Therefore, the sun quickly begins its deadly work of taking these oils off the surface of such roofings; and then continues to draw them out of the inside through the straw-like fibres of which the felt is composed, until the roofing becomes dry and porous and is no longer waterproof. J-M Asbestos Roofing is unlike other roofings, because its felts are made of stone fibres which are **solid.** These **solid** stone fibres defy the action of the sun's rays and positively prevent capillary attraction, thus hermetically sealing all of the oils so they must remain to do their duty indefinitely.

J-M ASBESTOS ROOFING

is not merely **one** sheet of water-proofed stone felt, but **several** layers cemented together with nature's wonderful water-proofer—Trinidad Lake Asphalt. This Asphalt is also hermetically sealed, making any escape of oils or asphalt impossible.

Prove for yourself that sun will soon destroy the water-proofed quality of ordinary roofings. Focus the rays of the sun through an ordinary sun or magnifying glass and note the results. This, in ten minutes, will show you what sun will do in a few months. This simple sun-glass test is as severe in its way as our famous blow-torch *fire* test. It will show up the shortcomings of a roofing *before* you pay out your money. Because of its stone nature, J-M Asbestos Roofing also never needs coating, and is fire-proof, acid-proof, rust-proof and rot-proof.

Most hardware and lumber dealers sell J-M Asbestos Roofing. Sold direct where we have no dealer. Write our nearest Branch to-day for sample of the curious Asbestos rock from which this roofing is made, and our handsomely illustrated Catalogue No. 303.

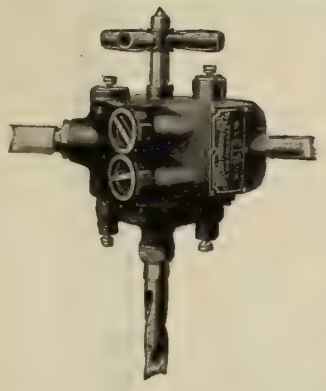
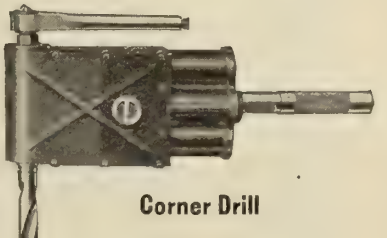
CLEVELAND AIR DRILLS



¶ Cleveland Air Drills are made in 43 styles and sizes and are adapted to all classes of work upon which Air Drills can be used such as Metal and Wood Boring, Reaming, Tapping, Flue-Rolling and Close Quarter Drilling.

¶ Cleveland Drills are fitted with Annular Ball Bearings on Crank Shaft which reduces friction and wear to a minimum.



Corner Drill

For close quarter drilling, made in two sizes, Nos. 38 and 49 with No. 3 and 4 Morse taper sockets.

FLOOR AND FLASK—CLEVELAND SAND RAMMERS—BENCH AND CORE

Light in Weight—Easy to Operate—High Speed—No Vibration.

Absolutely dust proof, no dirt can get through the Resilient Packing

Into the piston chamber or valves of the machine.

Made in 5 styles and sizes adapted to general foundry work. Always in stock:—All sizes of Riveting and Chipping Hammers, Portable, Bench and Centre Grinders, Valve Grinders, Drift-bolt Drivers, etc.

BOWES AUTOMATIC AIR HOSE COUPLINGS.

Over 1,000,000 in general use.

¶ They are instantly connected or disconnected.

¶ They are absolutely tight under all pressures.

¶ They are interchangeable in all sizes commonly used.

¶ They quickly pay for themselves by stopping costly mistakes.

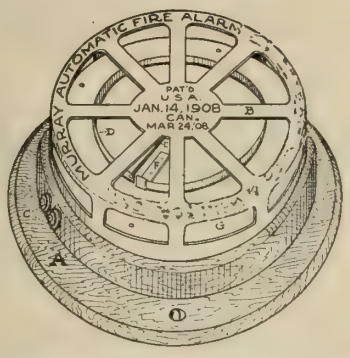
The Murray Automatic Fire Alarm



"Cheaper to have and never need, than to need *once* and not have."

Is a watchman that is always on duty and never goes to sleep.

Here's what a fire chief in one large manufacturing plant thinks of it:

The Murray Automatic Fire Alarm Co.
Toronto, Canada.

Dear Sirs:—

I have practically and thoroughly tested your Automatic Fire Alarm in every way pertaining to its use in factories and public buildings, and find it admirably adapted to the purpose for which it is intended, in effectively sounding the alarm.

Its simplicity and efficiency should at once commend it and secure its adoption and general use by those interested in automatic fire alarms.

JAS. CORBETT,
Fire Chief, Massey-Harris Co., Toronto.

The installation of this system is as simple as that of wiring ordinary call bells. Under the action of heat, when a predetermined maximum of temperature is exceeded, an electric circuit is closed and alarms given by the use of electric bells.

Write us for circular, and give us the chance to quote you price for your requirements.

SOME SAVING

TRADE MARK

They use 40% less oil.
They use a cheaper oil.
They use less metal.
They save cost of rebabbitting.

ALSO

It is cheaper and better than "Genuine" Babbitt.
It never runs hot.
It never cuts a shaft.
It never "breaks up."
It wears longer.
It stands the severe test on Rolls.
It is used on all of the Engine bearings.
It naturally absorbs less power.

COULD ANY BABBITT DO BETTER? CAN ANY OTHER DO AS WELL?

MANISTEE FLOURING MILL COMPANY,
Manistee, Mich., April 30th, 1912.

Magnolia Metal Co., New York, N.Y.
Gentlemen:—

We wish to relate the experience which we have had with Magnolia Metal in the past years. Our oil supply has been reduced fully 40%, and since using Magnolia Metal, we have not known what a hot box is, and are using a cheaper grade of oil. We have used a good many metals, including Genuine, and have found them to be either too hard, cutting the shaft, or too brittle, breaking up.

Magnolia Metal should be heated just hot enough to brown a white pine stick, keeping it thoroughly stirred before pouring. We use it in our rolls, a very severe test for babbitt, and on all the bearings in the engine. We do not use near as much babbitt as in former years.

Yours very truly,
MANISTEE FLOURING MILL CO.,

The Simplest and Most Economical System Known

THE

Sheldon Fan System

Consisting of

A Pipe Coil Heater, using exhaust or live steam, or both, which can be arranged for gravity return to a boiler located on the same floor.

A Blower, fitted with Sheldon Multivane Runner, which can be operated by any convenient power, most economically by a Direct Connected Engine, the actual operating cost of which amounts to only a small percentage of the heat in the system passing through the fan engine, the remainder being utilized in the heater, into which the engine exhausts.

Fan, Heater and Engine are centralized in one compact apparatus.

The Fan can be so arranged to take all or any part of its air supply from outside or inside the building, as desired.

The warm air is conveyed through ducts or flues and distributed throughout the entire building.

You Need a Machine Like This on a Dozen Different Jobs

It's a No. 2 Knight Milling and Drilling Machine

This machine is very rigid, powerful and accurate, so that close work may be turned out with a high degree of satisfaction, and in the shortest possible time. The adjustments are quickly and easily made. On a large variety of work it is possible to make a saving of from 20 to 50 per cent. in time, as compared with other machines.

The fact that hundreds of Knight Machines are now in use in this and foreign countries proves that they are not experiments. These machines are made in three sizes.

Briefly, the construction of the No. 2 Knight Miller is as follows:—Spindle of crucible steel, ground bearings; working surface of table, 29 x 8½ inches; feed, longitudinal and transverse; floor space, 60x68 inches; weight, crated for shipment, about 2,500 lbs.

Plant of Canada Iron Corporation, Ltd., Fort William, Ont.

By J. H. Williams*

The enterprise displayed by the management of the Canada Iron Corporation is clearly demonstrated in this plant, which consists of four foundries and a machine shop located at the head of the Great Lakes. The desire to meet the demands of our railroads for car wheels, and of our municipalities for cast-iron pipe, is further exemplified by the establishment of similar plants at various convenient distributing points throughout eastern Canada.

OF the six plants of the Canada Iron Corporation, Ltd., that at Fort William, Ont., is the largest and perhaps the most interesting, containing as it does the only pipe foundry in Canada operated on the continuous system. It is the leading industrial concern in the city, and gives employment to about 350 men. The various buildings occupy a site of 22 acres on the left bank of the Kaministiquia River, about 5 miles from the City Hall. They comprise machine shop, pattern shop and four foundries for the production respectively of general castings, car wheels, brake shoes and pipe. These four foundries, as may be seen from the plan on page 264, are arranged around three sides of a large cupola room. The latter is 110 feet long by 55 feet wide and contains five cupolas, the pipe foundry having two and the other foundries one each. It will be noted that the charging platform affords ample space for storage of coke, etc. There is a long inclined plane leading to ground level in the foundry yard, pig, scrap and coke being brought up this plane to the charging platform by cable haulage, instead of by the usual elevator. A spiral stairway leads from the charging platform to the ground floor of the cupola room, where are located a large wet cinder mill and the Sturtevant motor driven fans. The latter deliver blast at 13 oz. pressure. All cupolas when worn are patched with mica schist. This is brought in blocks from Pennsylvania and split up into thin slabs on the premises; being found to be both cheaper and more lasting than fire brick.

*Associate editor, Toronto.

Grey Iron Foundry.

The grey-iron foundry is on the north side of the cupola room, and in the same building as the wheel foundry, both being about the same size—115 feet long by 55 feet wide. The general foundry is served by a 20-ton Niles electric traveler, and the cupola is a 48-inch Colliau. In order not to occupy valuable space on the main moulding floor, the core ovens and core makers are accommodated in an annex on the east side of the building. The capacity of this foundry is 25 tons per day of 10 hours. Brass castings up to 300 lbs. are also made when called for, there being a pit fire in the core room annex for the purpose.

The Wheel Foundry.

The car wheel foundry is arranged on the circular floor system and has a daily output of 168 wheels, there being seven floors, each pouring 24 wheels. Each floor is operated by one man and a helper, and is served by a 1-ton jib crane. These cranes are now equipped with electric motors, although, at the time our photograph was taken, they were hand operated. The cupola is a 60-inch Colliau, which discharges into a delivery ladle of 8 tons capacity. The latter consists of a brick-lined steel shell mounted on trunnions and is tilted by a worm and worm-wheel operated by hand. On removal from the moulds, the wheels have the gates knocked off and are then taken on hand trucks to the annealing pits, where they remain three days. These pits, 32 in number, have each a capacity of 20 wheels. On leaving the pits, the wheels are cleaned, and then gauged by a standard M.C.B. wheel gauge; after which they are weighed and inspected. Each railroad

GENERAL VIEW OF PLANT FROM PIPE STOCK YARD.

has an inspector on the premises during the execution of its orders for wheels, and he has to O.K. every wheel before shipment.

Brake Shoe Foundry.

Brake shoes are moulded in a building measuring 85 feet by 50 feet, situated to the south of the cupola room. This foundry is greatly over-taxed at present, and is about to be very considerably enlarged. The present daily output is about 18 tons. All shoes are moulded on Pridmore draw-pattern machines, and the foundry is served by a 36-inch Colliau cupola.

The Pipe Foundry.

The pipe foundry, as previously stated, is operated on the continuous system and has an output of 55 tons of pipe per day. The building stands at the east end of the cupola room and measures 220 feet by 55 feet. It is served by three 10-ton Niles traveling cranes and presents a scene of great activity when in operation. There are two core rooms; cores up to 6 inches diameter being made on the north side of the building, while the larger cores are made on the south side. Each of the two cupolas is operated on alternate days and is in blast from about 9 a.m. to 6 p.m., during which period it melts 50-60 tons of iron. They are of the Baillot type, 36 x 42-inch elliptical section, and are extremely economical of fuel, the mixture used being 1 of coke to 13 of iron. They are very rapid melters, and can, when required, deliver as much as 9 tons of metal per hour each.

This foundry makes all sizes of pipe from 4 inch. to 24 inches diameter, sizes larger than this being manufactured at the company's plant at Three Rivers, Que. The iron flasks have trunnnions supported in small carriages which run on two rails in the moulding pits. Four-inch flasks are grouped six to a carriage; six and eight-inch flasks, four to a carriage; and all sizes over eight-inch, two to a carriage. In each pit there runs a long-link endless chain, with which the carriages can be engaged by a hook; in this way the moulds are moved down one side of the pit and up the other, thus going through a continuous cycle of operations. The approximate position of the flasks during ramming is indicated at A in the illustration on page 263. All pipes up to 20-inch are moulded bell end up, the main portion of the pattern being first inserted in the flask by the electric jib crane seen at F. The mold is then hand-rammed, after which the bell pattern is inserted and rammed. The bell pattern is then removed and the main pattern drawn. A man at the bottom of the pit now knocks out the door wedge and drops the cone pattern. A plunger of the same size as the bore of the pipe is next inserted in the mold, and a bucket of blacking is poured in on top, after which the plunger is pushed to the bottom of the mold by a long rod. In this way an even coat of blacking is distributed over the face of the mold. The latter is now ready to be dried and to this end the hook on the carriage is engaged with the endless chain and the mold drawn to the far end of the pit. Here, a transfer table brings it in line with the entrance to the oven, into which it is pushed by an electrically operated ram.

THE WHEEL FOUNDRY.

The oven, of reinforced concrete, 75 feet long, and heated by five coke fires equally spaced, is seen in the illustration; the molds emerging from the door marked (B). The core is now lowered by one of the overhead cranes, a chill ring inserted in the bell mouth, and a covering plate put on. The mold is then inverted on its trunnions and the core centred at the spigot end by means of three set screws and centreing clamps. The molds are next drawn by endless chain to the upper end of the pit—seen in the illustration, and a second transfer table returns them to the leg of the pit from which they started, where they are poured. A group of molds ready for pouring is seen at (G). The mold is

THE CHARGING PLATFORM.

next reversed, the cover plate and chill ring removed, and the overhead crane drops a long hooked rod right through the pipe. A triangular link is then dropped over the hook by which the crane pulls the pipe from the mold, afterwards placing it at the entrance to the pipe cleaning department as seen at (H). The flask now passes on to the position shown by letter (D). Here the dry sand is shaken out, and falls through a grating in the bottom of the pit, from which it is carried by an enclosed bucket elevator (E) to a horizontal conveyor, and thence to the mixers, to be prepared for further use. Meanwhile, the mold has gone forward to the position indicated by (A) and is again rammed up as before.

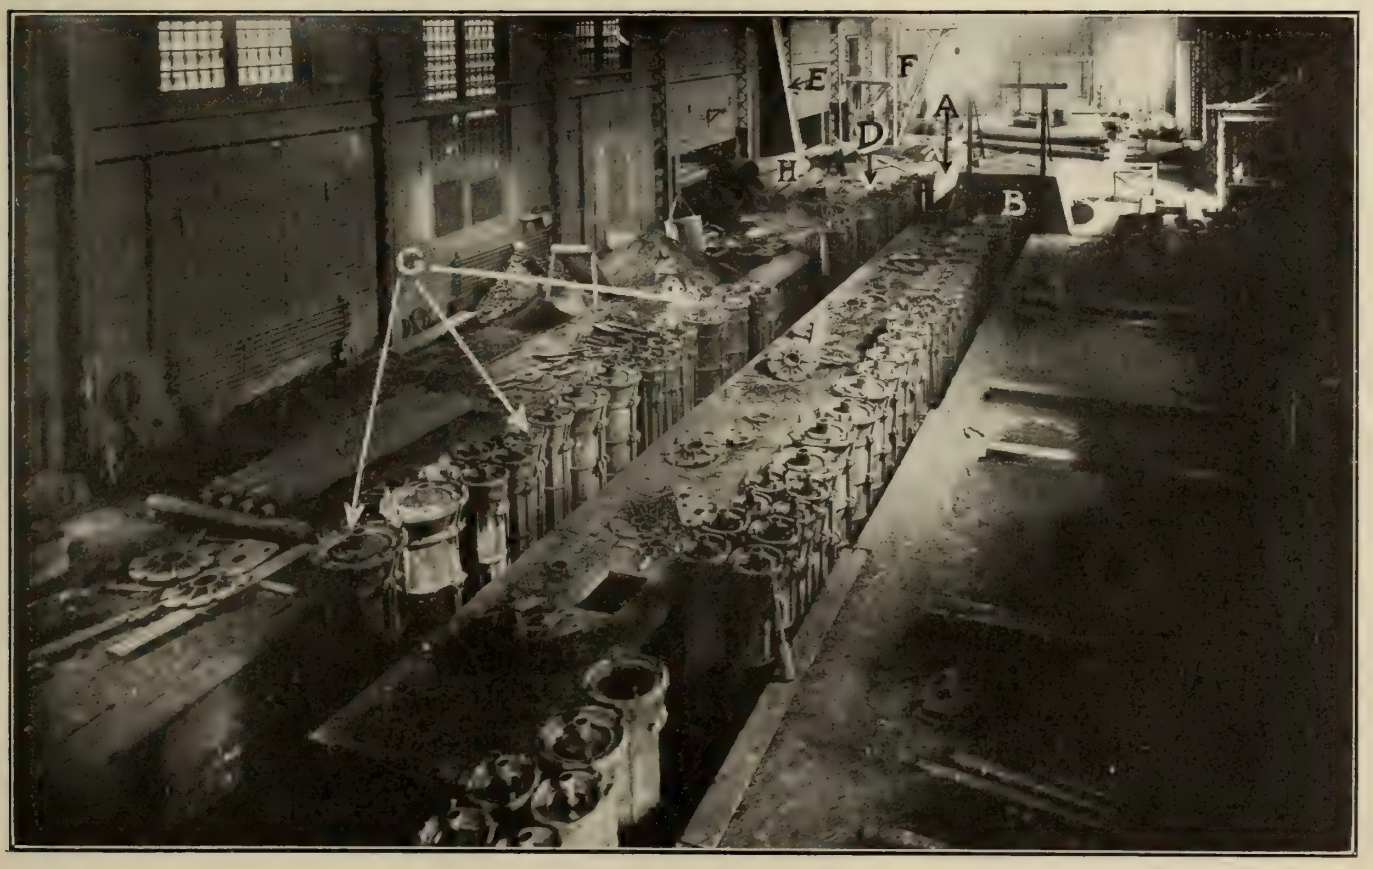
In the case of 24-inch pipe, the mold is rammed bell end down, and of course is also cast in this position, as is all pipe. In making the mold, the body portion of the pattern is first drawn. The flask is then raised, leaving the bell pattern behind. A socket core is next made separate on a plate, and the mold, after drying, is closed over the socket. The main core is now lowered into the mold to where it fits into the socket core, and is centred at the upper (spigot) end in the usual way. The mold is then ready for casting.

Loam for the pipe cores is obtained from a clay pit on the premises, and is brought to the core room by an industrial track. Two mud mills grind it up, one working on first coat and one on second coat mud. In making the cores, much labor is saved by the use of a 7 h.p. motor for revolving the core bars. The hay rope is all made on the premises, the hay being first damped in a wooden chamber fitted with steam jets, after which it passes to two hay-rope twisting machines. The core rooms are equipped with three 2½ ton travelers and contain twelve coke-fired core ovens.

PIPE CLEANING DEPARTMENT.

Pipe-Cleaning Dept.

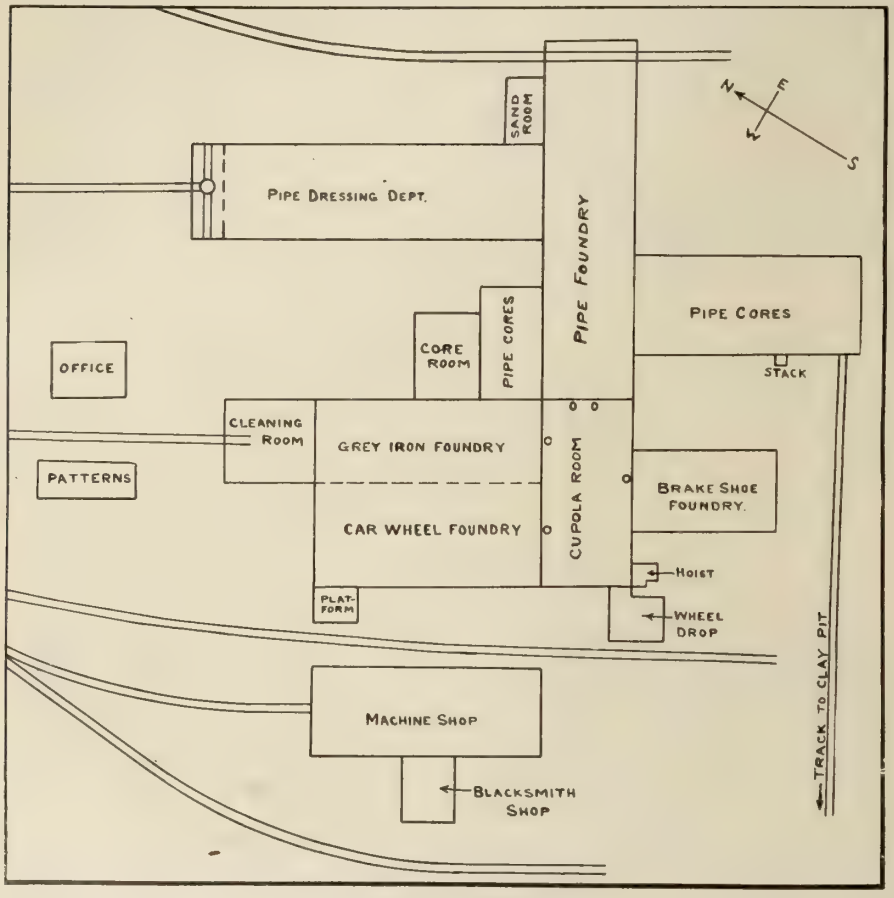
An illustration of this department is given on this page. The pipes are rolled in from the foundry on elevated rails and first of all have the remains of the core removed. This is accomplished by two special chain cleaners patented by Mr. C. L. Job, assistant manager of foundries to the Canada Iron Corporation. A chain is passed through the hole left by the withdrawal of the core bar, and is passed over two pulleys one at either end of the pipe. The two ends of the chain are then coupled by a hook and link. The pulleys are rapidly revolved from a motor driven countershaft and the flying chain quickly removes the hardened core. The two



INTERIOR OF THE PIPE FOUNDRY.

wooden A-frames, seen in the middle of the cleaning room, carry the idler pulleys, the driving pulleys being seen on either side against the walls. The A-frames are fitted with an adjusting device for increasing or decreasing the sag of the chain to suit varying diameters of pipe.

After having been cleaned, the pipes are rolled forward to the cutting off lathe, seen in the illustration. They are here reduced to standard length, several inches being cut off the spigot end, thus getting rid of the dirty metal that will have risen to the top of the mold. The pipes are removed from the cut-off lathe by the electric traveler seen overhead, and are rolled forward on the rails to a wood-fired heater, and then dipped in the tar vat. The next process is testing the pipes. For this purpose, there are two hydraulic testing machines by which a standard pressure of 300 lbs. per sq. inch is applied to each pipe. In special cases, the pressure can be increased to as high as 450 lbs. The testing machines are operated by an accumulator having an 8-inch ram and 9 ft. stroke. Having been tested, the pipe passes to a platform scale, and is then marked for weight and inspected, thereafter going to the stockyard.



PLAN OF WORKS.

Machine Shop, Power House, Etc.

There is a thoroughly well-equipped machine shop in connection with the plant. This building measures 137 ft. by 60 ft., and is used for general jobbing work, as well as for boring car wheels, making up pipe flasks, etc., etc. The shop is served by a 20-ton traveler and has a 150-ton hydraulic press for forcing car wheels upon their axles. The machine tools are all of up-to-date design and include a 56-in. boring mill; 72 in. radial drill; No. 2 milling machine; 36 in. gap lathe; 36 in. by 18 ft. shafting lathe; 18 in. slotter; 36 in. planer, etc., etc. In one corner of the shop there is an Ingersoll-Sargent motor driven air compressor which supplies power for the pneumatic tools in the different dressing departments, and for scrap breakers, elevators, etc. In an annex on the west side is located a small blacksmith department.

The power house is a small building situated some distance from the main plant and not seen in the plan on this page. It contains 2 Allis-Chalmers-Bullock motor generator sets, to operate which, 3-phase current at 2,200 volts, 60 cycles, is purchased from the Kaministiquia Power Co., Ltd. Each motor is direct coupled to its generator, and the latter has a capacity of 75 k.w., delivering direct current at 230 volts.

Other Plants of the C.I.C.

In addition to the Fort William foundries, the Canada Iron Corporation have five other plants. At Londonderry, N. S., they have a pipe foundry and steel foundry; at Three Rivers, Que., a grey iron foundry, pipe foundry and machine shop; at St. Thomas and Hamilton, Ont., they manufacture car wheels, brake shoes and general castings; and at Midland, Ont., they have blast furnaces, grey iron foundry and machine shop.

We are indebted to Mr. D. W. Davies, local superintendent at Fort William, for facilities granted for the preparation of this article on the occasion of a recent visit.

ANCIENT IRON.

SIR ROBERT HADFIELD has been able to obtain some specimens of the metal of the famous iron pillar at Delhi, and analysis shows the following composition: — Carbon, 0.08; silicon, 0.046; sulphur, 0.006; phosphorous, 0.114; iron, 99.72; total, 99.966. The iron percentage was determined, not taken by difference. The material is thus an excellent type of wrought iron, and the lowness of the sulphur percentage indicates that the fuel used in its manufacture and treatment, probably charcoal, must have been very pure. The metal contains no manganese which is remarkable, since that element is usually present in wrought iron. Sir Robert believes that this is the first time a complete analysis has been given of the material composing the Delhi Pillar. The specific gravity of the metal is 7.81.

INDUSTRIAL ACCIDENTS.

DURING the month of July there were 108 fatal and 272 non-fatal accidents recorded by the Department of Labor. This is an increase of 46 fatal and 38 non-fatal accidents compared with the record for June, and an increase of 10 fatal and 73 non-fatal accidents compared with July, 1911. Accidents recorded in which more than 2 workmen were killed, were, one as the result of a falling derrick at Kenogami, Que., on July 1, by which 7 men were killed; one by which 4 railway construction hands were killed by a premature explosion of dynamite on July 23, near Moberly, Ont.; one at Kenogami on July 25, by which four men were killed as the result of an explosion in a factory at Windsor Mills, Que., on July 8. Two workmen were electrocuted as the result of a falling pile driver coming in contact with live wires at Meaford, Ont., on July 18.

HYDRAULIC RIVETING*

By H. J. Hartley.

CONSIDERABLE diversity of opinion seems to exist regarding pressure per square inch of rivet section required for all classes of boiler work. At the present time the importance of having rivets to completely fill the holes is more fully realized and insisted upon than was the case twenty years ago. Under the old system of hand riveting, with the holes much too large for the size of rivets to be driven, doubtless much imperfect work was made. It was, and still is, a fruitful source of disaster, as rivets with loose fitting bodies, in addition to being imperfect themselves, allow undue weakness in the plates, owing to unequal and incomplete bearing surfaces. Hence, the strongest joint has been found by experiment to be that in which the area of the rivet body exceeds the net sectional area of the plate; the increased friction on the bearing surfaces and grip of the rivet heads on the plates more than compensating for the reduced plate area.

When riveted joints are being formed, the tendency is for the rivet to be upset on the end where the final head is being formed; the friction in the rivet hole resisting its flow to some extent. It is conducive to tight work to have a fillet under the head of the rivet which will, wedge-like, jam into the slightly countersunk hole; thus insuring, at least without the necessity of caulking, a watertight rivet, provided the plates composing the joint have been properly fitted and the rivet holes made fair and of proper size. The allowance, on increased sizes of rivet holes for heat expansion over the sizes of the rivets to be driven in first-class high-pressure boiler work, should not exceed the following fractional numerals, namely:—For ¾-in. rivets make hole 1-32-in larger; for ⅞-in., 1 in. and 1⅛-in. rivets make holes 3-64 in. larger; for 1¼-in., 1⅜-in. and 1½-in. rivets make holes 1-16 in. larger, and so on proportionately. All rivets should be heated to a medium cherry red at the head, and, if possible, to a dark cherry red at the points.

Cold Rivets for Tank Work.

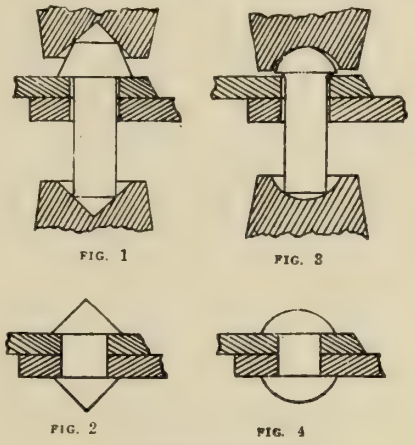
With regard to the pressures required for driving rivets cold in tank and stack work, I would recall some experiments made by Wm. Sellers & Co., between the compression platforms of their Emery testing machine. A number of ⅜-inch size rivets were subject to pressures between 10,000 and 60,000 pounds with the following results:

At 10,000 pounds the rivet swelled and filled the hole; at 20,000 pounds the head was well formed; at 30,000 pounds the rivet was well upset and headed; and at 40,000 pounds the metal plates surrounding the rivets began to stretch. This became more pronounced as the pressure was increased to 60,000 lbs. From these experiments, the conclusion might be drawn that the pressure required for driving and heading cold rivets is about 150 tons—300,000 pounds per square inch of rivet section.

Rivets for High-Pressure Boilers.

A series of tests to determine pressures for driving rivets in high-pressure steam boilers was made about the same time at the Baldwin Locomotive Works, by Mr. Vauclain, with the following results:

Six sets of 9-16-inch plates were selected and prepared for the tests, each set being composed of six plates, these being drilled for rivets varying in size by one-eight, from ⅝-inch to 1¼ inches in diameter. In the first set, the ⅝-inch



Hydraulic Riveting.

rivets were driven with a pressure of 25 tons; in the second set, the ¾-inch rivets were driven with a pressure of 33 tons; in the third set, the ⅞-inch rivets were driven with a pressure of 50 tons; in the fourth set, the 1-inch rivets were driven with a pressure of 66 tons; in the fifth set, the 1⅛-inch rivets were driven with a pressure of 75 tons; and in the sixth set, the 1¼-inch rivets were driven with a pressure of 100 tons.

The specimens when cut in half longitudinally through the rivet showed that where a pressure of 33 tons had been applied, the metal under and around the heads of the ⅝-inch rivets was indented or compressed. When 50 tons on both the ⅝-inch and ¾-inch had been applied, the same effect was noted, and so on up to 100 tons pressure.

In a second test similarly conducted, the rivet holes were punched instead of drilled; the only difference in the result being that the plates showed no indentation and the holes were all filled. The conclusion was that the suitable static pressure for ⅝-inch rivets is 25 tons; for ¾-inch rivets, 33 tons; for ⅞-inch rivets, 50 tons; for 1-inch rivets, 66 tons; for 1⅛-inch rivets, 75 tons, and for 1¼-inch rivets, 100 tons. Converted into pressure per square inch of rivet section, the figures in even pounds, would be approximately as follows:

Diameter of Rivets.	Pressure per Square Inch in Pounds.
⅝ inch	163,000
¾ inch	149,000
⅞ inch	166,200
1 inch	168,000
1⅛ inches	151,000
1¼ inches	163,000
Average	160,000

Example—Static pressure, 25 tons= 50,000 pounds, divided by area of ⅝-inch rivet=.3680=162,952 pounds pressure per square inch of rivet section. The average of the above pressures per square inch of rivet section is 160,000 pounds, which may be used in calculating the necessary pressures for rivets of other sizes. An experiment was also made in cold riveting, thus: A pair of plates were punched for ¾-inch rivets, which were driven into the holes with the same range of pressure, but it was found that the lower pressures were not sufficient to form the head, whereas the higher ones indented the plates. The writer has been working under the foregoing described conditions with the same riveting plant for about twenty years, doing all classes of steam-boiler work, varying in thickness of plate from ⅜ inch to 1¾ inches, and in rivet diameter from ⅝ inch to 1½ inches, with perfect success.

Terminal Impact of Ram.

There exists a condition, however, connected with hydraulic riveting, that is especially favorable to rivet compression and the making of tight work, which is generally not known or realized. It is due to an increased pressure at the terminal stroke of the ram over the initial stroke, amounting by experiment to be conditionally as high as 60 per cent. In other words, a static pressure of 1,200 pounds per square inch in an accummulator has shown on the gauge at the end of the stroke a momentary impact of 2,000 pounds per square inch. It will be understood that this increased terminal pressure is due to the surge of the accummulator on its sudden arrest at the end of the stroke and at the time when the rivet has become cooled from contact with the water-cooled dies and plates. Too much value cannot be given to this terminal pressure as a climax to perfection in hydraulic riveting; the effect being about the same as that of a second pressure on the rivet after partially cooling. This advantage is ever there and costs nothing to obtain, being altogether unlike the extra labor required

*Abstract of paper read recently before the American Boiler Manufacturers' Association.

on hand and pneumatic riveting to accomplish the same object—tightness, by having to partly drive a rivet and shift to the next in order to allow the first to cool; partly drive the second, shift back to the first and finish it, then go again to the last left unfinished, and so on throughout.

In order, however, to obtain the full value of the terminal pressure, it is necessary for the operator to exercise some skill in admitting the initial pressure to the ram. This is done by opening the valve slowly and sufficiently until the hot rivet has been well upset into the hole, after which the full pressure is applied. This will have the effect of accelerating the descending momentum of the accummulator, thereby causing a suddenly increased pressure on the rivet at the moment of its impact and the rebound, due to cushioning on account of more or less air in the water. This is more apparent with accummulators having small areas of pistons.

Shapes of Rivet Heads.

The accompanying illustrations will show the shapes of the rivet-beads generally in use by most boiler manufacturers.

Fig. 1 shows the shape of rivet-head mostly used by manufacturers. It also shows a rivet with pan-shaped head, ready to be driven with cone-shaped dies. The rivet being hot and the initial pressure bearing on the head and point, it necessarily follows that the rivet must flow into the dies before it gets bearing sufficient to squeeze it into the hole; the initial pressure being utilized in filling the dies.

Fig. 2 represents the shape of the rivet-heads after being driven.

Fig. 3 represents a rivet with round-shaped head, having fillet under head, heated and ready to be driven. It will be noticed that the dies on head and point bear more centrally; and while the die at the blank end of the rivet has a slight point bearing like Fig. 1, yet it is so little, due to the head end being solidily and firmly held in the die, that it may be said the initial pressure is bearing centrally on both ends of the rivet, thus permitting it to flow into the hole while filling the radial-shaped dies. In other words, the main feature is accomplished by the rivet filling the hole before the head is formed.

Fig. 4 represents a rivet driven with round-shaped dies in comparison with Fig. 2—cone-shaped dies.

Figs 2 and 4 show relative values of the two shaped heads, each having the same quantity of material. The round head is seen to be the better and also the stronger in the shearing section of the head. It is much easier to caulk a round-head than a cone-head rivet, if such should ever be required. The first indentation of the caulking tool on a round-head rivet forms an arch or backing to the tool, which has the effect of forcing the metal down to the plate, similar to caulking the edge of a seam, while the same operation on a pan and cone-shaped head has a tendency to curl up the thin edges of the rivet on account of insufficient metal above the caulking surface.

—⚙—

EMPLOYERS AND EMPLOYEES.

OF increasingly interesting value to the business world to-day is any feasible means of bettering the relationship between capital and labor. In the July issue of The Organizer, W. J. Chinneck has an excellent article on the fair treatment of employees by employers, in the course of which these suggestions appear:—

"Now that employers are beginning to realize that it pays to treat their workers honestly, just as it pays to treat their customers honestly, they are beginning to wonder how to do it. Fortunately, they have not far to seek. They have the example of a few wise men who thought this matter out years ago, and have evolved various schemes by which they and their employees are working for the success of the business which provides for them, instead of using up mental force in scheming to get the better of each other.

Full Co-partnership.

There is one scheme above all others which stands out as the best, if only it can be worked, and that is full co-partnership. Co-partnership is as far beyond profit-sharing as the latter is beyond no scheme at all, and to-day we are hearing a great deal about co-partnership. It is being advocated by politicians and by business men, but the meaning of co-partnership is not at all clear in the minds of a number of people, there being many different forms and many different degrees to co-partnership. It is as well to emphasize that co-partnership does not mean that payment for work done is made partly in cash and partly in shares or in kind. Payment should be entirely in cash, and the workers, or at least a large portion of them, being actual partners in the concern, should receive a dividend as shareholders in addition to full wages as workmen.

In the fullest sense of the word co-partnership also means that one partner should have just as clear a title to his invested capital as another partner, although the practicability of this does not always commend itself to the employer. It is exceedingly difficult in the case of a private firm or a private company to make such an arrangement as has been indicated. A workman having become a partner may leave and go to a rival firm, in which event it would clearly be desirable to regain possession of his shares on behalf of the other employees. In the case, however, of public companies, the value of whose shares is generally quoted, the adoption of full co-partnership is much simplified, because the capital is split up conveniently into units, and there are always a number of shareholders who are ready to sell at a price which the market itself fixes, and which is presumably a fair price.

Profit-sharing in Practice.

The plan adopted by one or two large public companies is that a certain share of the profits after paying dividends at an agreed rate, shall be distributed amongst the employees. This is the worker's share of the profit, and in order that they may become partners, it is necessary that they should apply the whole or a certain part of this bonus to the purchase of shares. It has sometimes been objected that employers make it obligatory that at least a portion of this profit should be applicable only to the purchase of shares, but it will be seen that unless this is done the scheme is not co-partnership, but profit-sharing. In order to get co-partnership you must provide for a proprietary interest, and the whole principle of co-partnership is to make the interests of the worker identical with those of other stock holders.

If a man wishes to take his bonus and not apply for shares he is not looked upon as the most desirable type of employee. In practice it is found to work out that the great majority of the employees want to buy shares. I was informed by a large employer, who has an arrangement whereby only half of the bonus need be applied towards the purchase of shares, that 90 per cent. was actually used by the men to increase their holdings. The acquisition of the shares is, of course, a simple matter when they are quoted on the market. They are bought at their value by an official on behalf of the employees, and are then held by the latter, who, in future, receive the dividends payable thereon in addition to the share of the profits which still goes to them each year as employees.

Encouragement to Thrift.

It will readily be seen that if the company is prospering, as profit-sharing companies generally do, the worker is adding every year to his capital, and gradually acquires a very respectable holding. The plan has been found to have a very great moral effect on the workers, and the man who previously

never dreamed of ever having property worth more than a few dollars gradually begins to see the value of thrift; and, in addition to the shares which he acquires more or less automatically, it frequently induces him to put aside a share of his wages, which is also used to increase his stock holding.

I have heard that Sir George Livesey, before he started co-partnership, went down to South Wales in connection with a local strike. He saw a man still working on a small locomotive in the docks and said, "And why are you not on strike?" The man replied, "I am a shareholder in the concern. Pretty foolish I should look to be striking against myself." This undoubtedly sums up the attitude of the workers where co-partnership has been in operation.

Co-partnership Mutually Beneficial.

Provided a fair day's wage is paid in the first place—and that is always contemplated by co-partnership—it makes the interests of everyone concerned identical. It means that the men are going to think for the business, and are going to be in favor of anything which makes for the prosperity of the business. From this point it is easy to get the co-operation of the men in effecting savings and in working honestly. It makes a man anxious that his mate should work as hard as he does, rather than he should not work harder than his mate. Under some schemes employees have the right to appoint representatives from amongst themselves to the board of directors, and this leads not only to co-operation but to good counsel, since, it is a means by which employers and their workers are led to understand each other's difficulties."

ELECTRIC BLOWERS ON BLACKSMITH'S HEARTHS.

As a considerable number of blacksmith's hearths are now fitted with blast provided by electric blowers, states the Electrical Review, the following incident may be of interest. In one case where a blast was obtained by an electrically driven fan, the delivery pipe was surrounded by a water jacket on account of the heat, and it was found that the temperature of this water rose practically to boiling point when the fan had been in operation for some time. On one occasion it was discovered that the draught was gradually getting weaker until it almost failed altogether. Suspicion was first of all thrown on the electrical portion of the gear, but this was found to be perfectly in order. The fan was taken adrift and the impellers and all parts of the casing were found to be in good condition.

On taking apart the ducts, however, it was found that the delivery pipe was burned through, which accounted for the loss of draught. This burning action was in its turn explained by the fact that owing to the heating of the water, rapid evaporation set in, and the level of the water fell below the level of the effective portion of the delivery pipe without its being noticed, with the result that the pipe was exposed to the full temperature of the escaping gases without any cooling action taking place.

A new pipe was fitted, and instead of the water in the surrounding jacket being poured in by hand at intervals as had previously been done, the water pipe was fitted with a ball cock, set so that when the water in the jacket got lower than was advisable, the cock was opened and allowed more to flow into the tank. This simple alteration prevented further trouble.

LOCOMOTIVE BOILER TESTS.

TWO low-water tests were carried out recently on locomotive boilers, one equipped with a Jacobs-Shupert sectional firebox and the other having the ordinary form of radial stay construction. In the radial stay type the flat side and crown and wrapper sheets are connected by radial stay-bolts, while in the Jacobs-Shupert type the flat plates are replaced by a series of corrugated channel-form sections riveted together with the flanges turned from the fire. Stay-plates or diaphragms are used instead of stay-bolts, and the rivets connecting the sections together serve also to connect the sections to the stay-plates.

In making the tests, which were carried out by the Jacobs-Shupert U.S. Firebox Company at Coatesville, Pa., two full-size locomotive boilers designed for high-speed passenger service were used, identical in size and design except that one had a sectional firebox while the other had one of the ordinary radial stay type. Both boilers were mounted in a field 50ft. apart, and were operated from a shelter 200 ft. from the nearer boiler. Oil was used for fuel, because of the danger to which a fireman shovelling coal would have been exposed. In the process of testing, each boiler was brought to a condition of operation closely approaching a maximum power of 1,400 h.p., which is equivalent to that required to haul a heavy passenger train at a speed of 60 miles an hour. The supply of feed water was then shut off, all other conditions remaining unchanged, and the water level gradually fell and exposed the crown sheet and other portions of the heating surface to the full effect of the fire. The boiler having the sectional firebox was tested continuously under these severe conditions for 55 minutes without developing any failure, although the water level fell to a point more than 25 in. below the crown sheet. The test was then discontinued because the small supply of water which remained did not evaporate fast enough to supply the necessary draught to maintain the fire. At the conclusion of the test the firebox of this boiler was apparently in good condition and ready for further service.

The ordinary radial stay boiler was then tested under identical conditions, and after the test had been in progress for 23 minutes, and the water level had fallen to 14½ in. below the crown sheet, an explosion occurred. The crown sheet, and the stays which held it in place became highly heated and pulled away from each other, with the consequence that the pressure in the boiler was released. The discharge of steam was through the firebox, and the force was sufficient to throw parts of the furnace in all directions and to lift the entire boiler, which weighed 40 tons, several feet above its foundations. The damage was such as to necessitate the reconstruction of the boiler.

The boiler having the Jacobs-Shupert sectional firebox carried between 215 lbs. and 225 lbs. for the first 27 minutes, and the pressure gradually dropped thereafter until it reached 50 lbs., at the end of the test. The steam pressure on the radial boiler varied between 220 lbs. and 230 lbs., and it was 228 lbs. when failure occurred. The gauges and the water level in the gauge glass were read by telescopes.

WELDED PIPES.

IN a recent discussion on welded pipes before the American Society of Mechanical Engineers, the fact was brought out that in commercial welded pipes the variations in thickness of wall, perfection of weld and other features of manufacturing, give rise to variations in the bursting strength which are of sufficient magnitude to render unnecessary any great refinement in the use of formulae. Relative strengths of steel pipes and tubes were indicated to be as follows:—For butt-welded steel pipe, 73 per cent.; for lap-welded steel pipe, 92 per cent.; and for seamless steel pipe, 100 per cent. In steel pipe the strength of the butt-weld appears to be about 80 per cent. of that of the lap-weld.

The relative strengths of wrought iron and steel pipe appear to be as follows:—Butt-welded wrought iron pipe is 70 per cent. as strong as similar butt-welded steel pipe; lap-welded wrought iron pipe is 57 per cent. as strong as similar lap-welded steel pipe.

Birth and Development of the Steel Works Engineer*

By A. L. Hoerr

The writer deals in an attractive manner with the rise to his present highly-respected position of the once more or less despised steel works chief enginer. The "Practical Men" used formerly to turn up their noses at the technically trained engineer and his staff of draftsmen; but that state of affairs is now a thing of the past. The paper incidentally gives many useful hints as to the economical operation of a rolling mill.

THE writer's experience began at a time when the rolling of steel was done to a large extent on mills that had been designed to roll iron, and were, therefore, not suited to the new requirements. Even newer mills, designed for the service, were often inadequate, partly because of the inexperience of the designers and partly because the demands of the business grew so rapidly that the mills could not be kept in line with them. The constant demand was for tonnage. Day by day this demand grew and the mills had to satisfy it. New and larger sizes of standard shapes were added to the rolling schedules as well as entirely new shapes; and as a result of these conditions, breakdowns were very frequent.

The Old Time Mechanics.

The men in demand were the master mechanics and their millwrights. Having been trained only in the hard school of experience, they knew little of books or calculations. Time in many cases could not be taken to determine the exact cause of a break, and the only remedy applicable was to make the new part stronger than the old. That this might and often did cause breakage in some other part of the mill or machine, could not be foretold, the main point being to get things going again as quickly as possible.

Foundations for new buildings or extensions, for shears, tables and other machinery were located in the field by means of a carpenters' chalk line, a straight edge, and a spirit level. The new building was planned about parallel to some existing building or track, but seldom with any thought of what might be needed in the near future.

Much of the machinery was designed in the pattern shop, and drawn full size on large built-up boards. Pattern-makers and machinists worked to these drawings and when the job was completed the drawing was erased with a plane and everything was ready for the designer once more. Repair parts were obtained by having someone who remembered the job, visit the pattern storage house and by the aid of some mysterious sense of direction, pick out the pattern. The machinist went to the broken or worn out parts for his sizes and very frequently got them right.

Improved Methods Evolved.

The mechanical men of that period deserve great credit for the work they did for the steel mills. Without engineering education or elaborate mechanical equipment, they designed and built the plants that earned the money to pay for the successive steps to our present efficient installations.

As larger mills were built, with elaborate mechanical mill tables, shear tables and cooling beds, the need of a more orderly system of working became apparent. In some cases, the master mechanic arose to the occasion and changed his methods, becoming, in fact, the engineer. In most cases, however, he leaned more and more heavily on the once despised draughtsman. The mechanical men could no longer take time to pick out the patterns, for there was other and more important work for them to do. The number of units in the plant had grown greatly, with a corresponding increase in the number of spare parts previously carried, and accurate drawings became a necessity. There had always been a few draughtsmen stuck in some dark corner of the plant, but they were not counted as of much importance. They were usually referred to in rather disrespectful language by the mechanical men, and if the truth be told, they often deserved it. The new conditions made necessary the employment of a large force of draughtsmen and also the organization of a field force to survey the ground, lay out the foundations for buildings and machinery, and supervise all construction.

The engineer, with this organization under his control, became a man of greater importance in the plant. He was called on to assist in many ways in the systematizing of numerous plant operations, beginning with a proper marking of his own drawings, and extending through the pattern shop into the foundries, machine shops and other finishing departments. Men from his department were detailed to follow the orders through the shops, expediting the transfers from one shop to another, interpreting drawings and making such changes as the development of the work made necessary. He could no longer be the designer of machinery for someone else to build, but on the contrary he must study carefully all of the processes involved and adapt his design to the facilities available.

In the field all locations for buildings and machinery were now carefully selected with regard to the future and many surveys and studies were made before excavations were started. In order that operations at widely separated points should have a definitely known relation to each other, standard base lines and elevations were established from which all surveys started. In many places the power end of the plant engineering grew up as a department distinct from the general engineering, while in other places they grew up together. In any case the problems were unchanged.

Power Plant Equipment.

The old equipment usually consisted of tubular boilers, simple, non-condensing engines and simple direct acting pumps. The electric power house was almost unknown except for a few belted arc machines. The boilers were all hand-fired and the ashes were taken out in wheelbarrows or carts. Coal was cheap and nobody objected to the smoke, which was accepted as the one best sign of prosperity. Into the midst of these conditions the engineer was projected in the course of his progress through the plant. The demand was not so much for changes which would save fuel as it was for changes that would make it possible to pull the loads with the existing engines and to get from the boilers enough steam to enable them to do it continuously. To meet this demand it was necessary to systematize the operations in the steam department. The firing of coal, cleaning of fires and blowing down the boilers in the various groups, were all arranged so as to interfere as little as possible with the production of a regular supply of steam both as to quantity and pressure. The boilers were cleaned more regularly and more thoroughly, and were carefully ex-

*Abstract of paper read recently before the Western Pennsylvania Engineers Society.

amined for both steam and water leaks. Steam pipe systems which had grown with the works and had been extended in all directions without any calculation as to pressure drop, were reconstructed so as to give shorter runs to the various consuming points, thereby making available a higher average steam pressure. This, together with the adjustment of valves so as to balance the work in the cylinders and reduce the back pressure, gave a new lease of life to many engines, apparently antiquated.

Introduction of Stokers.

As additions to the plant were made, water tube boilers and automatic stokers were introduced, sometimes with the mechanical ash handling machinery, frequently without. Compound engines were adopted with much hesitation at first, and in many cases were operated for years without condensers. Later, condensers were added, and until the advent of the low pressure turbine this was considered the most economical steam using combination possible. Some engineers maintain that this is still true.

The power plant grew greatly in size as motors replaced engines for driving the smaller auxiliaries in the plant, including the driving of shops, cranes, mill shears and tables, and the problem of the economical generation and transmission of electric power became of prime importance.

The reciprocating steam engine had this field to itself for a long time; but the high pressure turbine, the large gas engine using blast furnace gas and the low pressure turbine, have entered the field, in the order named, and are making strong bids for favorable consideration. Each, no doubt has its place, it being the engineers' duty to determine when and where they can be used to the best advantage.

Economizers and superheaters for the steam plant have been used rather sparingly; but the tendency now is to figure on them very generally, especially in connection with the utilization of waste heat from various metallurgical operations.

Engineer and the Power Plant.

In the plants where these various fuel saving devices were installed, it was quickly learned that their efficiency could only be maintained through constant and watchful supervision. It was not sufficient to instal a feed water heater; it was necessary to learn the water temperature from day to day. It was not sufficient to instal a compound condensing engine, it was necessary to indicate it at intervals to see that the load was properly distributed between the cylinders and that the condenser was maintaining a minimum back pressure on the low pressure piston. All other equipment required similar watching to see that its original economical operation was maintained. In some cases, as previously mentioned, the master mechanic assumed this new work and carried it on successfully, but in most cases it passed to the engineer. As there was no important part of the works that did not use steam, water or electricity, and as the engineer was now largely responsible for their economical production and distribution, there was no important phase of the plant's operation with which he was not brought in close contact. Although still looked upon by the so-called practical man as somewhat of a dreamer, he had an established place in the plant and was doing a work which became of more importance every day.

To-day the power problem is being given careful and detailed consideration in many large plants by separate engineering departments, organized for the purpose of collecting and interpreting data. These studies are of value for many purposes; among others, to determine the conditions under which most nearly continuous operation is assured; to determine the conditions for most economical operation; to aid in accurately determining costs of various products by a proper distribution of steam, water, electricity, etc. to the various departments, and to accumulate in available form, data from which the merits of proposed new equipment can be judged.

Power Plant Records.

To this end records are kept of the steam and water pressures, of the condenser pressures, of the temperatures of boiler feed water and of condenser water, of the weight of coal and water supplied to the boilers, of packing and pump valve service, of lubricating costs, and in short as nearly as possible of all variables that affect the operation of the plant. The records are supplemented by records of numerous boiler, engine and pump tests made under operating conditions. All of these data are then available for study by interested parties, either to throw light on certain cost sheet items or in connection with changes in equipment.

That the engineer has reached the limit of his development in plants of this character, the writer does not believe. Many men of engineering training and experience have reached important executive positions, and there are many reasons for believing that many more will do so in the future.

Expression has been given, however, more and more frequently of late, to a belief that will do much to prevent this. It has appeared in the engineering press and is frequently heard in the conversation of engineers. It is to the effect that the engineering profession is not properly recognized; that it does not receive financial rewards commensurate with the services performed, and that it does not receive the recognition in civic affairs which its interests demand and which its abilities merit. Much of this matter has about it a melancholy, disheartening sound. It professes belief in a most distressing state of affairs, blames it all on someone or something outside of the engineering profession, and looks for relief through some mysterious awakening of the other fellow which will enable him to see the engineer as the engineer now sees himself.

In the writer's opinion there is very little reason for such expressions and the instances in which conditions seem to be as represented, are almost entirely the fault of the engineers themselves. Financial rewards come to those who have for sale that which is in demand. It is not sufficient that a man be familiar with the laws of physics and mechanics or be able to calculate stresses in structures or solve problems in thermo-dynamics. Such knowledge is necessary for the engineer, but he may have it all and still be a mere calculating machine, differing from others only in height, weight or in the color of his hair. In an age when technical education is so easily obtained such knowledge alone cannot win large rewards. It is very easy to get men who can solve problems in mathematics and mechanics given the necessary data; but it is very difficult to get men who can assemble the data in proper form from the work in hand. It is easy to get men who can use steam tables and indicator diagrams in the solution of a power problem, but it is very difficult to get men who can see this power problem in the plant conditions.

It is also easy to get men who can sit at a desk and solve complicated problems in applied mechanics, but it is difficult to get men who can go into the works or through the offices and solve the constantly recurring problems in applied human nature. As engineers we have been taught that our profession is for the purpose of subduing the forces of nature to the service of mankind, but we have not been taught, to any considerable extent, that human nature is one of the forces to be subdued.

—⚙—

Every draftsman should realize the importance of specializing in one particular line of work. It is imposible for him to be a really good "all round" man;—like the members of other professions, he must choose the work for which he is best adapted and specialize in it.

Jig Mechanisms, Etc. (Additional), C.N.R. Shops, Winnipeg

By J. H. Williams *

In last month's isue of Canadian Machinery there appeared an article on the Canadian Northern shops at Winnipeg, which gave illustrated descriptions of many interesting labor-saving devices in use there. In the present article further jigs, etc., developed in these shops are fully described.

FOR supplementing the 2-ton hand travelers in the erecting shops, a number of jib cranes have been designed and constructed in the C.N.R. shops, Winnipeg. One of these is attached to each column in the erecting shop, as shown in Fig. 1. They are used for handling all front end work and in this way save much time that might otherwise be wasted while waiting for the traveler. These cranes have a radius of 14 feet, and are fitted with a 1-ton chain block. The boom will clear the smoke-stack of any locomotive on the adjacent pits and is also lower than the bottom of the crane runway girder, thus enabling the crane to swing partly round into the machine shop bay behind.

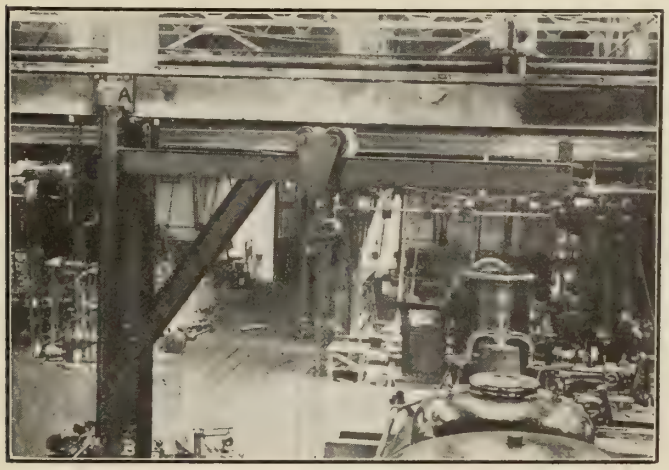


FIG. 1. ONE OF THE JIB CRANES IN ERECTING SHOP.

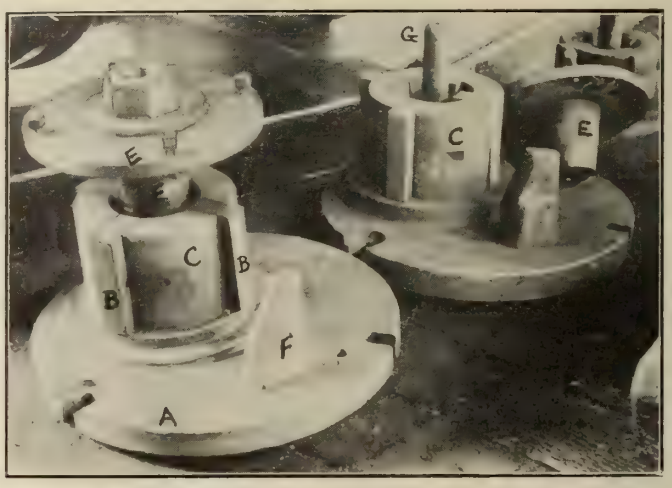

FIG. 5. JIG FOR TURNING ECCENTRIC PULLEYS.

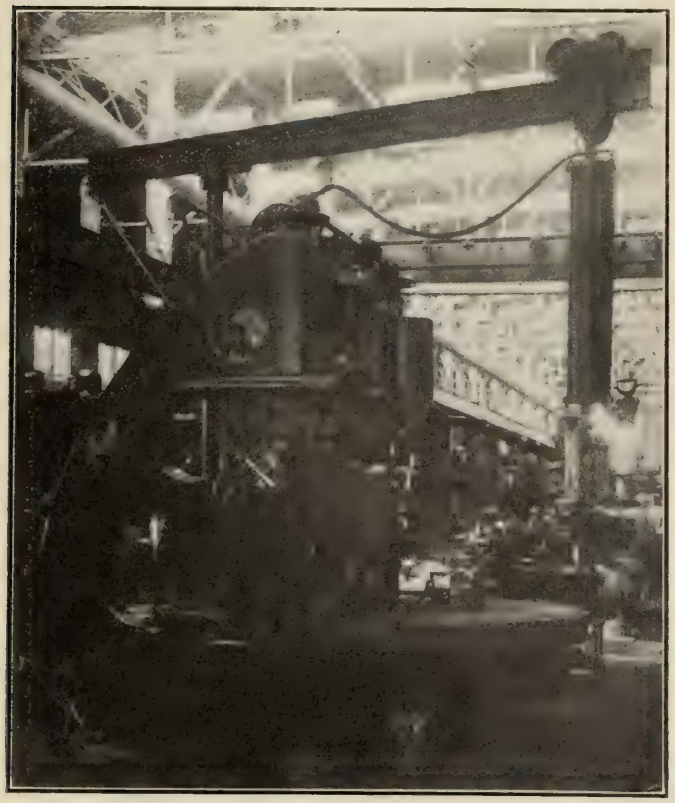

FIG. 2. CRANE AND AIR HOIST FOR INDIVIDUAL MACHINES.

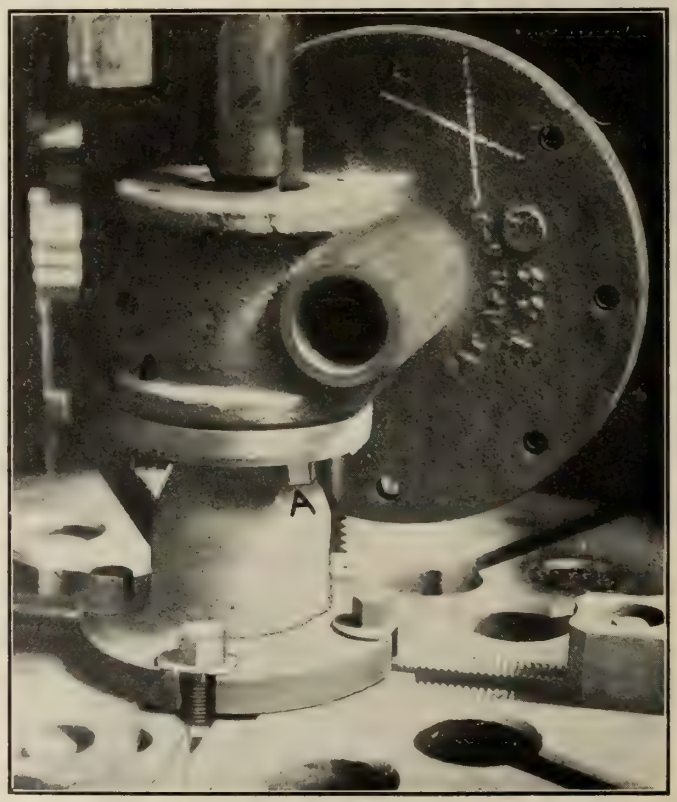

FIG. 3. JIG FOR BORING OUT VALVE BUSHING OF AIR PUMP HEAD.

The top pivot casting (A) is fitted with roller bearings and is bolted to the crane runway girder, while the bottom bearing (B) is fitted with a hardened washer slightly rounded on top to enable the

*Associate editor, Toronto.

crane to be swung easily. The various members are made from double channels, riveted back to back.

As stated in our August issue all the more important machines in the heavy machine shop are also fitted with jib cranes. Fig. 2 shows a 90-inch boring mill so equipped. These cranes are attached to the machine where most convenient, and carry a straight lift air hoist connected to the air line by a flexible hose. The boom of the cranes is made from 6-inch channels, while the post is of 4-inch pipe.

Jig for Air Pump Valve Bushing.

In Fig. 3 is seen a jig for boring out the valve bushing of air pump heads. The jig has two bosses, one at each end. One of these fits the hole at the centre of the table of a Bullard boring mill, while the other fits into the valve bushing, thus keeping everything central. The work is fastened to the jig by four set screws tapped into the holes provided for the cover studs, as may be seen at (A).

Jig for Planing Driving Boxes.

A jig for planing driving boxes two at a time is seen in Fig. 4. It is designed for repair work only, as the boxes are planed central and can thus only be planed in pairs; for instance, two main driving boxes or two trailer boxes, etc. A roughing tool in each head planes off the faces, and a special round nose tool is used for planing out the corners. The round nose tool is ground symmetrical about its vertical centre line, so that by swinging the planer head to right or left, the one tool planes both corners of the box.

Jig for Turning Eccentrics.

The method of turning the outside of eccentrics is shown in Fig. 5. The base (A) of the jig has a boss on the underside, turned to fit the centre of a boring mill table, and thus keeps the jig central. The mandrell (C) has four slots into which are fitted four steel gripping pieces (B). The latter are turned parallel on the outside, but have their inside faces bored taper to suit the shank of the cap (E). The latter is tightened down by means of the large central bolt (G), expanding the gripping pieces (B) into the bore of the eccentric pulley. The mandrell (C) is of course out of centre with the base (A) by the amount of the eccentricity of the pulley, a different jig being used for each eccentric throw.

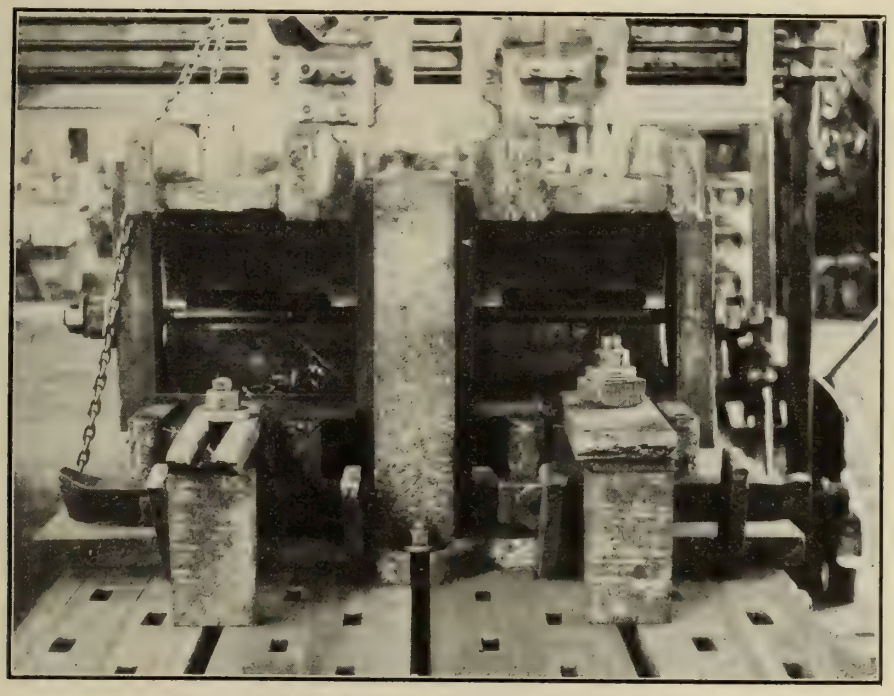

FIG. 4. PLANING TWO DRIVING BOXES AT ONCE.

On the base is a driving lug (F), placed so that the web of the eccentric bears against it and thus prevents the work from slipping under the cut.

OPERATING COST OF ELECTRIC VEHICLES.

A NUMBER of interesting opinions on the operating cost of electric vehicles is given in a recent number of the Electrical World. For instance, the effect of proper tire equipment on the efficiency of electric vehicles is of the greatest importance. Differences of 30 to 70 per cent. in car performance have been observed between heavy tires and the best electric car rubber treads. This means that with suitable tires, an electric pleasure car may double its mileage, and the life of its battery will probably be increased in about the same proportion, provided, of course, the car receives proper attention otherwise. This question of tires alone will often account for widely different energy consumption between two customers having the same make of car and doing approximately the same work.

From reliable data covering operating expenses over a period of three years the following figures were quoted for 1-ton and 1½-ton wagons:—Average days in service per month, 24½; average miles per day per wagon, 29½; average kilowatt-hours per mile, 0.491. Car operating expense per mile:—Oil and other supplies, .6c.; general repairs, 1.4 cents; electric energy at 4 cents per kilowatt-hour, 2 cents; tires, 1.62 cents; batteries, 1.70; total expense per mile, 7.32 cents.

NEW MATERIAL FOR HIGH-SPEED PINIONS.

THE increasing use of high-speed machinery employing a positive drive has created a demand for pinions that possess adequate strength, yet operate noiselessly. Where metal gearing is used for operating high-speed machinery, no matter how well the teeth are formed or how accurately they are cut, noise is nearly always the result. When deluged with oil, and quite new, such gearing may run quietly, but when even slightly worn, the noise created is most objectionable. This has led to the substitution of various non-metallic materials in gear trains, and for this purpose, paper and rawhide have been used with some success. It is claimed, however, for a new material named "Fabroil" that nothing approaches it either in preventing noise in gearing or in general utility.

Fabroil Pinions.

Fabroil pinions, which are patented, are manufactured by the British Thomson-Houston Co., Rugby, England. They are formed from a special woven fabric compressed into a solid mass under several tons pressure, and held together between steel flanges either by threaded sleeves, as in the case of the small pinions, or by threaded studs, as in the case of the larger examples. The strength of these pinions is said to be greater than that of any other non-metallic pinion, and, owing to a measure of flexibility possessed by the teeth, which allows of good bearing surface across the full width of the face, they will run at high speeds without variation and absorb shocks which would be sufficient to strip the teeth of a cast iron pinion or to cause a brass pinion rapidly to lose its shape, and consequently to give trouble.

The teeth are cut to the 14½ deg. involute system, according to Brown and Sharpe's standard. After the blanks have been assembled and machined, they are impregnated with oil, and after the teeth are cut they are again impregnated with oil, which renders them self-lubricating, impervious to moisture, and able to resist atmospheric changes. They are also said to be proof against injury by vermin and insects. Fabroil also remains unchanged when heated. Machines equipped with Fabroil pinions are operating under many conditions of service, from driving a small light tool to operating heavy punch presses and shearing machines at the works of the manufacturers, who inform us that they have demonstrated their thorough reliability and have given them more severe tests to prove this than those to which pinions are ordinarily subjected, so that any weaknesses, should they exist, might be shown up. Under all tests so far given, Fabroil pinions have, so we understand, figured well, not only in comparison with other non-metallic pinions, but as compared with metal pinions. As an indication of the tooth strength of Fabroil pinions, Lewis formula using cast iron contacts will apply.

The pinions are supplied from 2-in. outside diameter, progressing by ¼-in. to 12-in. outside diameter and from 1-in. face progressing by ¼-in. up to 12-in. face.

BELTS FOR LUMBER WORKING MACHINERY.

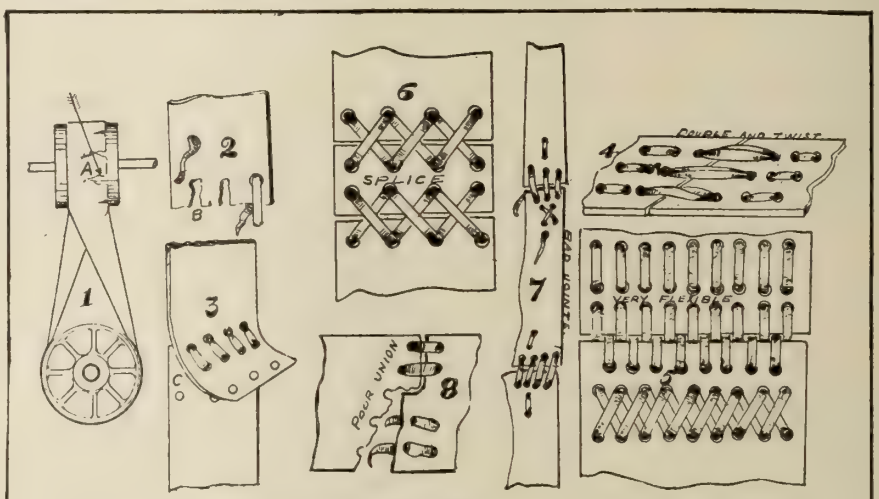
BELTS employed in the operation of woodworking and finishing machinery are exposed to more severe atmospheric conditions than the common belt. Ordinarily, belts are confined within apartments in mills or shops, where there is a fair protection for them; but in the lumber industry one may find belting running in the open, conveying power from an engine established in the woods to the lumber cutting machinery, also not sheltered, except, perhaps, for a crude roof thrown up over them. The belts of exterior lumber cutting service are subjected to rain, sun and dust. These three factors combine to ruin a belt in a few months, unless precautions are taken to overcome some of the troubles. There is often considerable building of sheltered passages for belts in the fixed plant; but when the sawing plant is of the portable character there is not much time or material wasted in erecting covered ways. For these reasons belts of lumber working yards are likely to have numerous defects in them.

Fig. 1 shows the manner in which an exposed belt usually breaks up. The constant heating, drying, wetting and chafing of the uncovered leather results in hardening and cracking along the edge as at A. Of course, lubricants can be applied to soften the leather, and these will impregnate the fiber and help to some degree, but even the oils become non-effective as time passes and dust gathers in quantities on the surfaces. The dust hardens and is worn down to a smooth gloss on the wheels and the surfaces of the belting. When a belt gets to the stage shown, it is time to replace it, although the chances are that the new one will go to pieces in a similar way in time. In order to overcome this danger, a covered passageway should be erected.

It is becoming more common to use covered ways for running belts in lumber yards. In some cases, the portable plants are provided with adjustable sheet metal runways through which the belt may be passed when the outfit is set up. Exposed belts decay rapidly at the joints, so that in time the holes may pull out as shown at B, fig. 2. When the holes break out in this manner, the end must be clipped off to present a fresh surface. The holes, however, pull out again, and once more a piece is cut off. This takes some of the leather out each time and makes the belt shorter, necessitating a piece being spliced in. The exposed belt of the lumber yard is liable to break apart at the joints, as at C, fig. 3, because of loosening of the cementing stuffs due to moisture. In order to prevent the joint from severing entirely, a row of lacing is put in, as shown. Fig. 4 shows a triple system of lacing. Six rows of holes are punched and the centre laced with the double twist type of lacing. This distribution of laces would make a firm grip under ordinary conditions; but when a belt is in a weakened condition through moisture and general exposure the rotting leather will pull out at the holes regardless of everything.

The system of lacing shown in fig. 5 is somewhat elaborate. The workman had experienced trouble with the belt breaking at the joint. He had adopted several methods, still the laces pulled out or the ends of the belt tore off. He then devoted considerable time to the complicated belt sewing illustrated. He put a series of holes, all close together, and when he got to the middle he arranged the laces to fit alternately above and below the joint, thereby making a most pliable union.

Fig. 6 is given to show one way employed by the mechanics of a certain lumbering establishment of making a union with a splice piece inserted. It will be noticed that the crosses are confined to one side. Often in inserting a piece in a belt to make up for the bad ends that have been clipped off, the laces are made straight and crossed on the same side. This mixture of straight and crossed laces always develops trouble.



Methods of Mending and Splicing Belts — An Elaborate Mend

BELTS FOR LUMBER WORKING MACHIN ERY.

In fig. 7 is shown the kind of belt that should be avoided, for the reason that it is patched and remade in places. In case a belt has to be used after it is patched a number of times, pains should be taken to have the joints cut evenly and laced. If the splice is uniformly made, it should not hinder the run of the belt; but if the splices are poorly made, as in this figure, the belt will give endless trouble. Belts in use on struggling machines like this are sure to militate against the performance of good work. Often belts on important machinery in lumber yards operate in as bad condition as shown in Fig. 8. In case a belt thus united has much work to do, the strain will quickly tear open the union; but if the work is light the patched joint may run on indefinitely, but giving poor service.—American Lumberman.

Machinery Display at the Canadian National Exhibition

The annual Canadian National Exhibition at Toronto has once again come and gone and as in previous years attracted enormous crowds. The Machinery Hall once more proved far too small, and this apparently deterred some concerns from exhibiting, as several prominent engineering and supply firms were not represented.

EXHIBITORS.

The Canadian Hart Wheels, Hamilton, Ont., showed a large selection of their Beaver brand of razor hones and corundum grinding wheels.

The Boiler Repair and Grate Bar Co., Toronto. were demonstrating their 20th Century shaking and dumping grate bar.

The Jas. Morrison Brass Manufacturing Co., Toronto, were located in the Process Building where they had a large booth in which were displayed numerous and varied specimens of the work turned out by them. The exhibit included pressure gauges, counters, injectors, marine engine-room telegraphs, etc.

The Canada Metal Co., Toronto, were located near the south entrance to the Machinery Hall, where they had a good display of their well-known products, including lead joints and plumbers supplies of all kinds, fuse wire, copper ingots, battery zincs, pig lead, spelter, etc. In addition, samples of their many brands of Babbitt were shown ,among which the Harris Heavy Pressure occupied a prominent place.

The Dodge Manufacturing Co., Toronto, occupied a large space with their well-known products for power transmission, including split wood pulleys, bearings, hangers, etc.

The Garlock Packing Co., Hamilton, had on hand a full line of their packings under charge of H. G. Fletcher, manager of their Toronto branch.

The Chicago Pump Co., Chicago, had on view their automatic electric condensation pumps for drawing condensation and air out of heating systems, and automatically returning the water to the boiler. The system is operated independently of the boiler pressure, no vacuum pump being used.

The A. R. Williams Machinery Co., Ltd., Toronto, had a good selection of machine tools including a flat turret lathe (Jones & Lamson type) by the Stevens Co., Galt; a Kearney & Trecker No. 1 Milwaukee miller; Schuchardt & Schutte No. 1 gear hobber; Gould & Eberhardt 14-inch shaper, etc., etc. They were also demonstrating the "Champion" tool holders made by the Western Tool & Mfg. Co., Springfield, Ohio.

The Canadian Morehead Co., Woodstock, Ont., were represented by Mr. Geo. W. Cole, who was kept busy demonstrating and explaining the special features of Morehead non-return, return, vacuum and condenser steam traps.

The Robt. Mitchell Co., Ltd., Montreal, were demonstrating the Wood's Oiler, which has recently been put upon the market. This cylinder lubricator is suitable for steam engines, gas engines, air compressors, etc., and has many novel features. It is a force feed lubricator, yet there is no pressure in the sight glass or oil tank. Lubrication is effected by a pump which is positively operated by the steam pressure in the engine cylinder and which delivers the oil to the steam pipe in the usual way. The manner of accomplishing this is extremely interesting and well worthy of investigation.

The Canadian Machinery Corporation, Ltd., Galt, Ont., had on view some of their leading lines of iron and woodworking machinery. The former included a 16-inch shaper, and an 18 in. by 8 ft. standard engine lathe, while the latter comprised a standard chain mortiser, 16-inch jointer with Falls automatic undercut attachment, mitre saw, and 8 ft. glue jointer.

John Millen & Son, Montreal, had a large show case display of Coventry noiseless chains for driving purposes. They also showed a novel application of these chains to automobile change speed boxes. Another prominent feature of their exhibit was a group of Cyclone high-speed chain blocks ranging in capacity from ½ to 40 tons.

Wm. & J. G. Greey, Toronto, had a large show of flour mill machinery, among which were an improved oat-flaking machine, a dough mixer and adjustable dough divider for cutting up dough into equal portions. The exhibit also included steel conveyor buckets, hand trucks and general mill furnishings.

The Canadian H. W. Johns-Manville Co. exhibited their asbestos products, roofing material, fibre conduits for underground wiring, J-M and Red Seal dry batteries, and high temperature cements for furnaces.

Jones & Glassco, Montreal, showed numerous examples of Renolds' Silent Chain for which they are sole Canadian Agents. This driving chain is well-known to all power users. Among their other exhibits were specimens of the Kenyon patent inter-stranded cotton driving rope, made by Wm. Kenyon & Sons, Ltd., Dukinfield, Manchester, Eng. They also showed Skefko Ball Bearings.

D. K. McLaren showed their well-known British oak-tanned leather belting, besides steel split pulleys and other mill supplies.

The Borden-Canadian Co., Toronto., were kept busy demonstrating the Beaver die stocks for threading and cutting pipe. These die stocks have adjustable dies which do not require to be changed for the different sizes of pipe. Thus, the 6-inch die stock will cut all sizes of dies, and moreover, can be operated by one man.

The Dominion Belting Co., Hamilton, Ont., showed driving and conveyor belts made from their "Maple Leaf" stitched cotton duck.

The General Machinery Co., Traders Bank Bldg., Toronto, showed Luitwieler Pumps in operation.

The Chapman Double Ball Bearing Co., Toronto, showed many examples of their well-known annular ball bearings and double ball thrust bearings. One large bearing in particular attracted much attention. This, a 6-inch double annular ball bearing, has recently been added to the company's regular line.

The Carborundum Co., Niagara Falls, N.Y., showed numerous examples of their carborundum and Aloxite grinding wheels.

The Elmira Machinery and Transmission Co., Ltd., Elmira, Ont., showed shafting hangers and bearings, split wood pulleys, etc.

Cowan & Co., Ltd., Galt, Ont., had an extensive exhibit of their well-known lines of wood working machinery.

The Lumen Bearing Co., Ltd., Toronto, showed a great many samples of well-made die-castings on view.

La Societe d'Air Liquide, Montreal (formerly R. J. Levy), were doing oxy-acetylene welding and cutting in a tent outside the Machinery Hall. The company manufactures oxygen and liquid air and supplies complete oxy-acetylene equipments. They also do welding and cutting work by contract.

The James Morrison Brass Mfg. Co., Toronto, were located in the Process Building. Numerous and varied specimens of their well-known products were in views, such as steam and hydraulic pressure gauges, engine counters, injectors, stop valves, marine engine-room telegraphs, etc.

The Linde Canadian .Refrigeration Co., Montreal, exhibited a belt-driven 20-ton ammonia compressor, operating in the Dairy Building. It was employed to care for the exhibits of the Farmers'

Dairy, the City Dairy, the Harris Abattoir, and others.

The Cling-Surface Co., Buffalo, were distributing literature and demonstrating the merits of their well-known belt-dressing.

The Tallman Brass & Metal Co., Hamilton, made a good display of their Arctic Babbitt Metal, as well as of brass rods and tubing, brass castings, brass signs, etc.

The Consumers Gas Co., Toronto, had a Crossley gas engine in operation, besides a number of gas accessories of various kinds. A furnace for hardening or annealing high-speed steel was shown, and also a gas fired rivet-heating furnace. This exhibit was in the Gas Building.

The Positive Clutch & Pulley Works, Toronto, exhibited a number of their wood-rimmed pulleys, with pressed steel spokes and malleable iron hubs. A features of these pulleys is their absence of windage. A combined jaw and friction clutch was also shown. In this friction, pieces made of fibre are employed to gradually pick up the speed of a shaft or pulley under load, after which the positive jaws are thrown into gear, the friction being disengaged at the same time. The whole operation is controlled by one lever.

The Ontario Wind Engine & Pump Co., Toronto, showed a large number of Strickney gasoline engines. One of 7 h.p. rested on two rollers of iron pipe without being bolted down. In addition, it had the covers removed from both journal bearings, and ran all day with very little vibration. The governor can be adjusted while the engine is running, and has a wide range.

The Crescent Oil Co., Hamilton, Ont., showed lubricating oils, split wood pulleys, "Alligator" flexible steel belt lacing, etc., etc.

Baines & Peckover, Toronto, showed "Lincona" balata belts, tool steels by B. K. Morton & Co., Sheffield; and babbitts by the Atlas Metal & Alloys Co.

S. F. Bowser & Co., Toronto, were located in the Process Building, where they exhibited their well-known self-measuring pumps. These pumps are a great convenience in a large engine room, garage, railroad roundhouse, etc., where large quantities of oil are handled. An adjustable stop on the pump rod varies the travel of the plunger, and so controls the amount of oil delivered at each stroke.

Chapman & Walker, Limited, Toronto, had a large exhibit of motors and other electrical equipment.

The Canadian Boving Co., Toronto, showed a single cylinder Bolinder Semi-Diesel engine of 12 H.P. in operation A feature of this type of engine is its extreme simplicity, there being only three working parts exclusive of the fuel pump and governor.

The Northern Electric Co., Montreal had a very handsome booth in the Industrial Hall, where they exhibited their telephones, fire-alarm, apparatus, etc.

The Dearborn Drug and Chemical Works, Chicago, were explaining the merits of the Dearborn treatment of boiler feed waters.

H. L. Peiler & Co., Montreal, exhibited a full line of Bundy steam traps, Mason regulators. Their booth was shared by

The Engineering Specialties Co., Toronto, who had on hand an assortment of "Everlasting" blow-off valves, "Flexible" tube cleaners, etc.

WORLD'S OUTPUT OF PIG-IRON.

MESSRS. James Watson & Co., Birmingham, England, have compiled their annual statistics of the world's production of pig-iron. They place the output for 1911 at 63,668,926 tons, a decline compared with the previous year of 1,938,867 tons, but 3,303,146 tons more than in 1909. In the United States there was a shrinkage of 3,649,201 tons in 1910, while in Great Britain there was a falling off of 498,107 tons. Germany on the other hand, makes rapid progress, an increase of 2,617,459 tons on 1910 being shown, and on 1909 of 741,787 tons.

The following table shows the output of the different countries for the past three years:—

	1909 Tons	1910 Tons	1911 Tons
United States	25,795,471	27,298,545	23,649,344
Germany	12,917,653	14,793,325	15,535,112
Great Britain	9,664,287	10,216,745	9,718,635
France	3,544,638	4,032,459	4,408,025
Russia	2,817,000	2,956,000	3,521,000
Austria and Hungary ..	1,947,300	1,990,684	2,089,867
Belgium	1,632,350	1,803,500	2,072,847
Sweden	443,000	604,300	633,800
Spain	420,000	425,000	435,000
Canada	677,000	740,210	824,345
Italy	147,000	343,600	253,322
Japan	161,020	162,000	162,000
India	39,350	35,933	49,205
China	74,000	120,000	110,000
Mexico	58,859	45,000	70,090
New South Wales	26,762	40,487	36,384
Total	60,365,780	65,607,788	63,668,926

GASOLINE MOTOR TRUCK MAINTENANCE COST.

A PAPER was recently presented by Mr. Louis Ruprecht, before the summer meeting of the Society of Automobile Engineers, at Detroit, on the "Cost of operating Gasoline Motor Trucks." Quoting a few of the figures given, the depreciation may be at from 10 to 15 per cent. per year, the tire value being deducted from the cost of the complete vehicle and the tires considered independently.

Driver's wages on a half-a-ton delivery wagon may be assumed to be about $2.75 per day, and on larger trucks from $3.00 to $4.00 per day.

Garage charges, including only the washing and storing of the vehicle, are on an average from $240 to $300 per year, according to the size.

Tire cost should be figured on the basis of a life of 8,000 running miles, as guaranteed by the makers.

Gasoline cost may be taken as about 11 cents per gallon, although at times it may be somewhat higher.

Oil may be assumed to be 30 cents per gallon, and one gallon of oil will be sufficient for 50 to 125 running miles according to the size of the vehicle.

Insurance will be from $100 to $250 per year, according to the size.

Repairs and replacements should be figured up to 3 cents per mile in the case of heavy trucks. This figure is based on extensive records.

Compiled Data.

Based on these figures a table has been compiled which gives, in the first place, the fixed charges per day for different sizes of vehicles, and in the second the additional running cost per mile. For example, the cost of operating a six-ton truck, all charges included, 45 miles per day, will be $\$6+(0.1540\times45) = \$12.93$. The figures presented by the author also show conclusively that wherever a large tonnage is to be handled, it is of the highest importance to use a few large units instead of many small ones.

Size of Vehicle	Fixed charges	Increment Per mile.
1,000-pound	$5.07	$0.0686
3-ton	5.33	0.0860
5-ton	5.60	0.1253
6-ton	6.00	0.1540
7-ton	6.15	0.1718
12½-ton train	7.40	0.2070

LABOR UNREST ON INCREASE.

INDUSTRIAL conditions were seriously disturbed by labor disputes during July, the number in existence in that month being considerably greater than the number existing during June. The number actually commencing however, during July compares favorably with that of the previous month. In all 46 disputes were reported to the Department of Labor, an increase of 9 as compared with June, and an increase of 28 as compared with July, 1911. About 17,000 employes were affected by these disputes, as compared with 15,000 during June, and 19,000 during July, 1911. A termination of the Garment Workers' strike in Montreal occurred during July, which caused a resumption of operations by more than 4,000 employes after nearly two months of idleness. Few of the disputes commencing during July were individually of serious consequence as factors in disturbing industrial conditions.

Trade Journal Publicity--Its Meaning to Gas Engine Makers *

By E. R. Shaw **

The place and power of the trade journal is here clearly demonstrated, and while the occasion on which the address was delivered particularized the field somewhat, it will be quite evident on reading over the paper that the contents are applicable to manufactures and industries generally.

WHEN I was honored with a place on the programme of this Convention and assigned my subject, I was afraid that from such a long title you would suspect a long talk. I am not going to emulate a darky preacher who had the reputation of talking so long that nobody could keep awake, and who talked so loud that nobody could go to sleep.

Potency of the Trade Paper.

The most potent factor in our industrial and commercial development during the past generation has been the Trade Paper. It has rapidly increased in importance in every field of endeavor. No other class of publications are read as thoroughly and earnestly as Trade Papers. We can all agree to the proposition that there is an inexorable principle in nature that is constantly seeking to establish an equilibrium, or in other words, to adjust things in such a way that friction will be reduced and waste effort abolished. The Trade Paper may be defined as a finely adjusted implement of twentieth century progress that automatically selects and attracts only the interested, and eliminates all others. Like other economic conveniences, specialized publications are unappreciated and discredited by some, but to the constituency which it seeks to aid, it goes modestly and noiselessly and greets its readers with a radiance of intelligence because it is one of the hand-maids of education. As a people we are looking for the best systems, for the most economical methods, and our progress as a nation is because of the fact that we have less conservatism, less routine in our way of doing things than have other nations.

In the material world there are no accidents recognized, and if we will but trace to their antecedent cause those things which we call results, we will find a well-defined reason for everything. Success is won by application of substantial reason—not chance. The Trade Paper is the embodiment of all that is substantial, the foundation of that which is safe and secure. Its pages reflect that which has been tried and found true. Its influence can not be overcome nor its power adequately estimated, for its force is always along the lines of least resistance.

Trade Paper a Sale Producer.

There are about as many methods of developing sales as there are methods of developing power, and from the conditions it can be determined which method fulfills the requirements most accurately. The specialized Trade Journal is a thing of life and vitality which conforms to the economic laws of marketing in the special field it serves. It is an automatic selector of possible buyers and a developer of latent want into commercial demand. If rightly hitched to the load it is the modern engine for marketing those products whose customers can be segregated from the general public. The Trade Papers are the most effective and economical customer finders and sales makers in any field, because they are the publications which appeal to that field and to no other. Such publications, and only such, offer a practically wasteless way to place your product before those whose interest finds expression in orders.

Trade Paper Advertising.

Of the millions of people in this country only a few thousand perhaps have any possible use for gas engines and their auxiliaries, and you can not afford to advertise through general mediums to the millions who have no interest in your product in order to reach the few thousands who are your possible customers. A salesman's time is too valuable to use for any of the work that can be done by advertising. So says a man who makes a business of training salesmen. The man who says "There is nothing like a good salesman to move your goods," thinks he has dealt advertising a body blow with that half-truth, but the man who has really thought about it and the man who has tried the combination says, "There is nothing like a good salesman and good advertising." That's the whole truth.

What may be called the machine work of selling, getting attention to the product, telling what it is and what it will do, and thus awaken interest and create desire—this is work for the printing press, because the printing press can do it in a wholesale or quantity way much cheaper than it can be done by salesmen. This work thoroughly done leaves the salesman only his proper function to perform, leaves to him the skilled hand and head work of showing the buyer just how the product fits his individual and perhaps unusual requirements, quoting prices, terms and closing the order.

An Aid to Salesmanship.

How often have you invited a salesman in and given him a chance just because you had heard of his goods—had noticed, perhaps without consciously reading, the advertising of his house, and had been favorably impressed? Advertising does get attention and creates interest and desire now as never before, and the salesman who once regarded it with contempt or as a rival—as something that was after his job and would get it if he didn't watch out, now looks upon it as his most efficient assistant, as one of the tools of his business. He is the first to fight for it if it is in danger of being cut off or reduced. He even makes suggestions for its improvement, just through an enlightened self-interest, and the same motive moves him to see that advertising gets the credit for the work it has done in his territory—work which only he has had the opportunity to see.

Suggested Line of Action.

Give your salesmen the help they are entitled to. Save their time, which is your money, by making your goods known—favorably known through advertising in the papers that are read by the people who use your goods. Use enough space to tell your story well and in an interesting way. Use enough space to impress the unknown prospect, who has no other way of judging you, that "here's something worth while; the man who makes it must believe in it, or he would not spend money advertising it."

Do that and you are well on your way toward the favorable acceptance of your product. How much is enough space? That depends on the product—how it is marketed, competition, distribution, a dozen things, perhaps, on which it is easy to get safe advice. If a full page is your size, a half-page might be extravagant. Maybe a quarter-page is enough, but decide to do it right, and do it right soon.

---

*Read before the National Gas Engine Association, Milwaukee, Wis., June 20, 1912.

**President Federation of Trade Press Associations in the United States.

EDUCATIONAL VALUE OF ENGINEERING MAGAZINES.*

By W. D. Robins.**

IN the engineering magazines, edited and published by present-day methods, there is a great deal of information which no ambitious man engaged in mechanical work can afford to overlook. A large and valuable part of this information is of such a character that it could not be obtained from any other source without a great deal of time and trouble. While familiarity with what is being done in the line of his profession is of undoubted value to the engineer who has attained a position involving important administrative or technical responsibilities, it is certainly of no less value to the draftsman or student whose experience is more limited.

Intelligent Study Desirable.

Without intending to imply that there is any agency equal to actual experience for developing and forming the sound, level-headed judgment required in all branches of engineering work, it is the purpose of this paper to show that the knowledge of current practice, in a particular line of work, which can be obtained by intelligent reading of the engineering magazines, will be of great value in applying to actual cases the fundamental principles of design or operation. Though all engineering work is governed by mathematical laws, the application of these laws to actual work is by no means the exact science which their mathematical origin would seem to indicate. This is due partly to incomplete knowledge of the laws themselves and partly to the variable character of the materials used and conditions of operation.

Editorial Features Current Practice.

Every student of machine design is familiar with the numerous formulas containing variable factors, such as factors of safety, safe stresses, empirical coefficients, etc., which represent the results of practical experience or scientific experiments. These factors, as given in the text books, often vary between wide limits; the proper value to be used for a given case being left largely to the judgment of the designer. By substituting in a formula the dimensions or quantities given in a magazine article describing a machine and then solving the formula for the variable quantity, an idea can be obtained of the value used in current practice for the class of work under consideration. The extent to which this practice may be carried out depends upon the opportunities of obtaining magazines and the time and mental energy remaining after the performance of the daily work. If it is not practicable to use the magazines in such a detailed manner as indicated above, it is still possible to use them to determine the application of principles in a more general manner.

Descriptive articles may show that for the same purpose, one power plant uses a direct-acting steam pump, another an engine-driven centrifugal pump and another an electrically-driven plunger pump. One bridge may be built of masonry, another of steel, and another of re-inforced concrete. Ship propelling machinery will be described in many combinations, from the torpedo-boat destroyer with oil-burning water-tube boilers and steam turbines, to the Western river steamer with flue boilers and simple engines exhausting to the atmosphere. By the habit of determining, as far as possible, from descriptive matter given, the reasons for the adoption, in any case, of the particular apparatus employed, a certain degree of familiarity with the subject is sure to be obtained. The practice of looking for the controlling factors of design is likely to develop the ability to determine what constitute these factors, and also what their relative importance is.

Engineers of high standing and varied experience have stated that the two most important branches of knowledge for a man engaged in engineering work are the principles of mechanics and the properties of the various materials used in the construction and operation of his work. Now, the principles of mechanics do not change; but materials do change, for the properties of materials continually vary with improved methods of manufacture, new materials and combinations of materials are being used, and familiar materials are being put to new uses. Much valuable information concerning materials and their uses can be found in the magazines long before it gets into text books.

The Advertising Pages.

Again, the advertising matter in an engineering magazine contains a wealth of useful up-to-date and instructive information, because the modern methods of advertising depend more upon directing attention to the character and efficiency of the article itself than upon making vague and spectacular claims for it and enveloping it in an atmosphere of mystery, as was too often the practice in the past. When it is remembered that the use of unsuitable material for pipe-joint gaskets or valve-stem packings might seriously impair the commercial efficiency of a large power plant, it is apparent that any material or appliance used in engineering work, however trifling it may seem at first glance, needs careful study and inspection.

In conclusion, the writer wishes to emphasize the fact that nothing in this paper is intended to belittle the importance of actual experience. It is intended, rather, to suggest methods of finding information of real practical value in a lot of reading matter which is often put aside as containing nothing but dimensions and statistics.

COST OF OPERATING A 4-TON MOTOR TRUCK.

THE Howards Co., New Haven, Conn., has been operating a 4-ton motor truck, built by the Kissel Motor Car Co., Hartford, Wis., and the data compiled on this cost indicates that in 12 months the truck will effect a saving of $1,600, as compared with the cost of maintaining three two-horse teams, formerly required to do the company's hauling. This saving is effected after considering as depreciation the entire cost of the truck. A comparison of the cost of maintaining three double teams and operating the 4-ton truck is as follows:

THREE DOUBLE TRUCKING TEAMS.

Cost of six horses at $300	$1,800.00
Cost of three wagons at $450	1,350.00
Cost of six harnesses at $35	210.00
Cost of keeping horses, $25 a month	1,800.00
Repairing harnesses, wagons, etc.	100.00
Interest on investment	336.00
Drivers' salaries, $12 a week	1,872.00
Total	$7,468.00

"KISSEL-KAR" FOUR-TON TRUCK.

Cost of 4-ton truck	$3,800.00
Gasoline, 2,400 gals. a year at 10c.	240.00
Oil, 156 gals. a year at 23c.	35.88
Drivers' salary at $18 a week	936.00
Amortization, 10 per cent. on $3,800	380.00
Interest on investment	380.00
General overhaul, once a year	150.00
Total, truck	$5,921.88

This shows a balance in favor of the motor-driven vehicle of $1,546.12.

During the first few months of its operation the truck averaged 484 miles and the gasoline and oil consumption daily were 7.6 gallons and 2 quarts, respectively. It will be noted that in the figures covering the cost of operating the truck that in addition to charging the first cost of the truck, 10 per cent. is charged for depreciation. On this basis the economies effected by the use of the 4-ton truck are much greater than the figures indicate. These figures demonstrate that a truck can replace 8 to 10 horses and still effect an annual saving of approximately $2,000. If the truck owner had written off 20 per cent. for truck depreciation and estimated the truck's life at five years, a net saving of $3,000 per year would have been effected.

Vol. VIII. SEPTEMBER, 1912 No. 9

INDUSTRIAL UNREST.

THE growth of industrial unrest has proceeded at such a rapid rate and has assumed such formidable proportions as to constitute a menace so undesirable and fraught with truly unlimited destructive possibilities as to make both capital and labor pause in their imbecile efforts to paralyze one another.

The insistent tendency in the direction of combines, mergers and trusts, and the ultimate attempted concentration of power and administration in the persons of a few, is neither a sign of a country's prosperity nor a compliment to the morality, the intelligence and wisdom of the promoter autocrats who are personally involved. Again, while trades unionism is a necessary, yea, even a commendable institution, in the various spheres of industrial operation, it is common knowledge that, as in the trust sphere, autocracy and dictatorship of a select few have many times precipitated much unnecessary suffering and distress.

Stated briefly, capital and labor—the trusts and the trades unions, are warring for control of production, and where the latter is not directly involved, the trusts are seeking to acquire control of public utilities and services. It has been pointed out, that labor in seeking to regulate over production is unwittingly keeping up the selling price of commodities, and being, as all employes are, the principal and majority purchasers, they are demanding a set of conditions more or less inimical to their own best interests. The reasoning is sound philosophy, but human nature is fickle, having, as yet, little faith in, and being pretty well convinced that the odds are heavily against an increase in the spending power of the nimble dollar. Production will, of necessity, have to be controlled, and if trust control of public services and utilities is a criterion, which, unfortunately, we must make it, then no one can shut their eyes to the possibilities. Trades unions, on the other hand, have as little need to bolster up men within their ranks who are incapable exponents of a particular profession as they have those who will only use them as a lever to amass wealth.

In each sphere, there are undesirables; in the former, those who cannot work at a particular trade with sufficient aptness and intelligence to earn a living; and in the latter, those who will not, even if they could, work to attain the same end. It is perhaps one of the most distressing features of our 20th century civilization that most of us are in our wrong niche, and, therefore, incapable of furnishing our biggest quota of usefulness.

In a prominent marine engineering establishment, employing about 1,000 hands, 500 of whom probably were apprentices, much difficulty was experienced by a lad of eligible age in securing an opportunity to become one of the latter. The works 'rules stated very definitely that sons and daughters or other near blood-relatives of an employe would be admitted in preference to all others, and only in the event of the above supply source failing, was an outsider eligible. Needless to say, the supply did not fail, and as showing, in addition, how strong the desire for the perpetuation of the profession of marine engineering was implanted in the hearts of these parents, and how they compassed the certainty of their offspring being assured of an opening as apprentice, public opinion credited a child's name as having been entered on the company's apprenticeship list just as soon after birth as his Christian name had been determined. There is neither "trust" or "union" apparent in the foregoing relationship between employer and employe; as a consequence harmony prevailed.

The dictatorship of both Trust and Union almost regulates, to-day, who shall live, and a to-morrow may yet dawn in their regime when it will be determined who shall be born.

THE FOUNDRYMEN'S CONVENTION AT BUFFALO.

FOUNDRYMEN throughout Canada and the United States are looking for the coming Annual Convention and Exhibition at Buffalo, in the latter part of the present month, to exert on their chosen calling a powerful and progressively forward impetus. Past experience has shown that widespread benefits have accrued to the trade through the medium of this combined function, and it is little wonder that the very liveliest interest among the members of the craft, operative and administrative, begins to make itself evident as the week for universal interchange of ideas and study of methods and apparatus developed in the elapsed interval, draws near.

The opportunity to visit the American Foundrymen's Annual Convention and Exhibition is one that every person connected with the trade directly and indirectly should grasp, and we are right in saying that those who have once availed themselves of the privilege are intensely desirous of being present again. The fact that Buffalo, N.Y., is the location of this year's Convention and Exhibition, makes possible for Canadian foundrymen a more or less extended visit, and from inquiries made, there is every prospect of a large and representative delegation being present. We will, as usual, have a booth in the main exhibition hall, at which Canadian visitors and others will be made especially welcome.

MACHINE SHOP METHODS AND DEVICES

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

EVERYDAY PROBLEMS OF THE MACHINE SHOP.

By J. H. R.

THE accompanying sketches are for illustrating the application of trigonometry to some of the everyday problems met with in the machine shop. While in many cases these questions would be dealt with in somewhat different fashion from that here shown—partly due to the mechanic not being conversant with the method of procedure, and largely to the practice of some tradesmen in resorting to trial means, the intention of the writer is to discuss the practical application of a few of these principles, and help to some extent those who are unfamiliar with this subject.

As the circumference of a circle bears a certain relation to its diameter, so also do the sides of triangles to their included angles. By the study and practice of the trigonometrical functions, we can determine the distance between any point on one side, to any point on the adjacent side of any particular angle, and vice versa.

Problem 1.

The sketch, Fig. 1 illustrates a square, shaped or milled on the end of a shaft. This square is to fit a 2¼ inch spanner as shown, and there is required the diameter of blank necessary, before the squaring operation. Now, if we know the length of any two sides of a right-angled triangle, we can find the third by involution and evolution. The sum of the squares of the two shorter sides equals the square of the longest side, or hypotenuse. The required diameter in this case is the diagonal, a — d.

Referring to the figure, o — c = c — b = 1.125 inches. Squaring o — c = 1.125 × 1.125 = 1.2656. Adding o — c and c — b = 1.2656 + 1.2656 = 2.5312. Extracting the square root for length o — b = √ 2.5312 = 1.591 inches. Diagonal, a — d or diameter of blank = a — o + o — d or 1.591 × 2 = 3.182 inches or 3 3-16 inches nearly.

Again, o — b = the hypotenuse of the right-angled triangle ocb; then, by the formula pertaining to the trignometric functions. Hypotenuse =

$$\frac{\text{side adjacent}}{\text{cosine}} = \frac{\text{o—c}}{\text{cosine of ang. 45 deg.}}$$

$$= \frac{1.125}{.70711} = 1.591 \text{ inches.}$$

Then diameter of blank = 1.591 + 1.591 = 3.182 or 3 3-16 inches nearly.

Problem II.

Fig. 2 shows another frequent visitor in the machine shop. The distance across the flats of the hexagon is to be 2¾ inches. It is required to find the diagonal measurement or diameter of blank from which the hexagon can be shaped or milled.

By the same process as that performed in the previous problem, we find the required size.

Half the distance across the flats or o — c = 1⅜ inches; then, by the formula,

$$\text{hypotenuse} = \frac{\text{side adjacent}}{\text{cosine}} \text{ or o —}$$

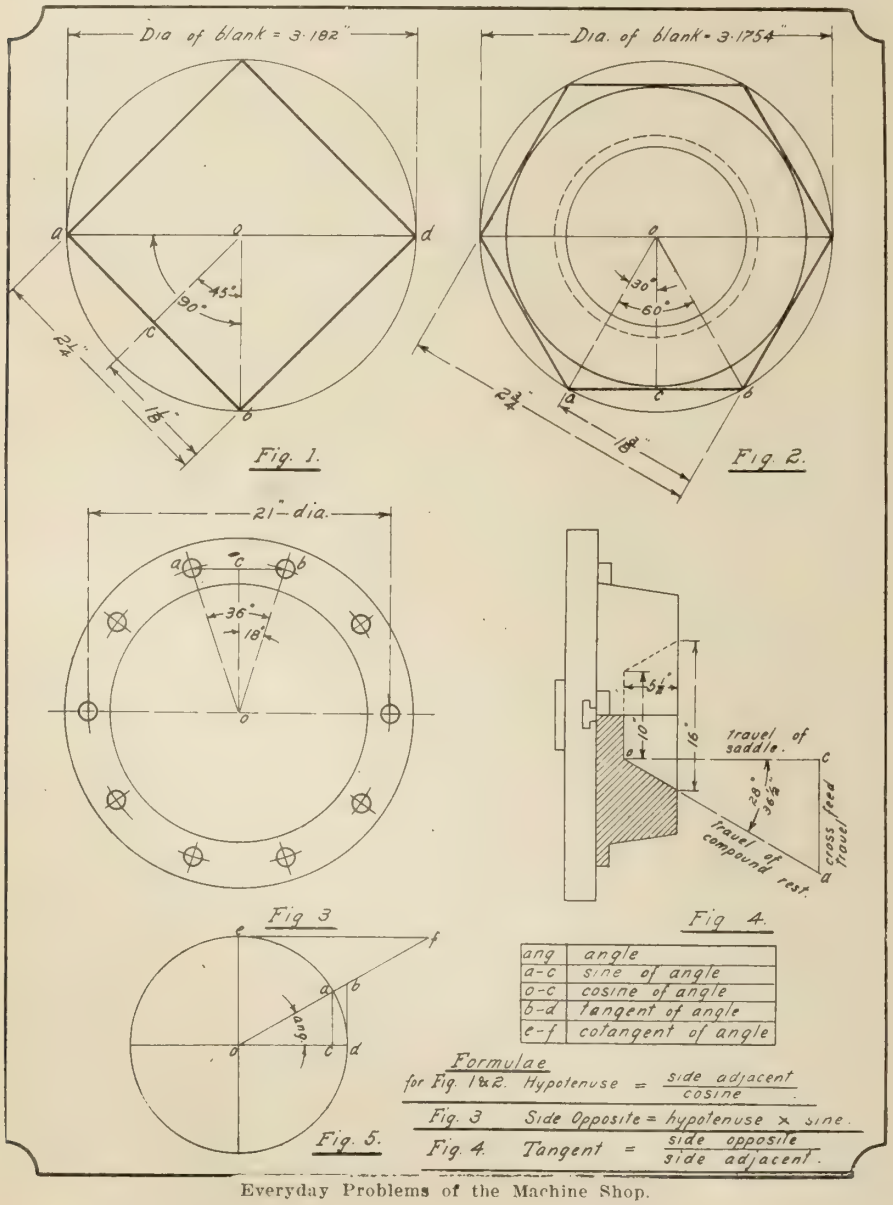
$$\text{a} = \frac{\text{o—c}}{\text{cosine of 30 degs.}} = \frac{1.375}{.86603} =$$

1.5877 inches for diagonal a — d. The diameter of necessary blank being 1.5877 × 2 = 3.1754 or .3 11-64 inches nearly.

Problem III.

The spacing of holes around a circle is another problem often encountered in the everyday routine of the average mechanic. Fig. 3 shows a circular plate in which ten equidistant holes are to be drilled on a 21 inch circle.

The length of trammel required is the distance a — b. Bisecting the included angle of 36 degs., so as to form the right-angle triangle ocb, necessary for solution, we get the angle 18 degs., hypo-



Everyday Problems of the Machine Shop.

tenuse o — b, and the side opposite c — b.

Radius of the circle = 10.5 inches; then by the formula, side opposite = hypotenuse × sine, or o — b × sine of angle 18 degs. = 10.5 × .30902 = 3.2447 inches. The step of the trammel or distance a — b = 3.2447 × 2 = 6.489 or 6 31-64 inches nearly.

Problem IV.

Sometimes we will have a job for the lathe or boring mill which calls for a movement of the compound rest or swivel head. When definite sizes are given, it becomes necessary to use a little judgment or calculation to determine the right angle at which the cutting tool must travel in relation to the axis of the work. Fig. 4 shows a large casting on the face plate of a lathe. As is shown, three measurements are given—diameters of top and bottom and the depth.

In order to find the angle of the compound rest with the axis of the lathe spindle, the angle of operation is extended to illustrate more clearly the method of procedure, and the angle aoc is the required result.

Depth or side adjacent, o — c = 5½ inches.

Half the difference between the top and bottom diameters equals a — c or side opposite = 3 inches. Then, by the formula, tangent =

$$\frac{\text{side opposite}}{\text{side adjacent}}$$ or tangent of angle aoc = $\frac{a-c}{o-c} = \frac{3}{5.5} = .54545$. From a table of trigonometric functions, we find corresponding to .54545, the angle 28 degs. 36½ inches nearly.

The diagram Fig. 5 exemplifies the relative positions of a few of the trigonometric functions, with three of the formulae necessary for the solution of the above questions.

SIMPLE DRILL FIXTURES.

By Donald A. Hampson.

AFTER a special wire forming machine had been put into service, it was found that two parts, the rod and the head shown in the drawing Fig. 1, needed rather frequent renewal. The head, as will be seen, was held by a pin which passed through one side of the rod, cutting out about 1-5 of its diameter . As the head and the rod did not wear out equally it was important to have some means of drilling both parts so they could be made up and used interchangeably. The writer was detailed to make up a dozen of each piece and as the easiest way of doing so, took the liberty of making a couple of simple jigs.

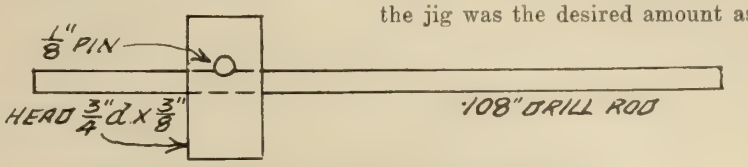


FIG. 1. SIMPLE DRILL FIXTURE—THE WORK.

Fig. 2 illustrates the jig made to drill the centre hole in the head. A piece of drawn steel was chucked and the hole for the head and the one for the

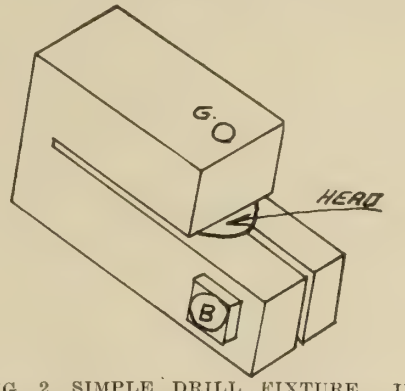

FIG. 2. SIMPLE DRILL FIXTURE. JIG TO DRILL CENTRE HOLE IN HEADS.

guiding of the drill (G) made concentric with each other. Two saw slots were cut, a binder screw (B) put in, and the piece case-hardened. For drilling the pin hole, two pieces of flat stock were selected. The lower piece was drilled and slotted for the head and the guide hole (G) put in; see Fig. 3. The upper piece was drilled and slotted for the drill rod and was carefully located

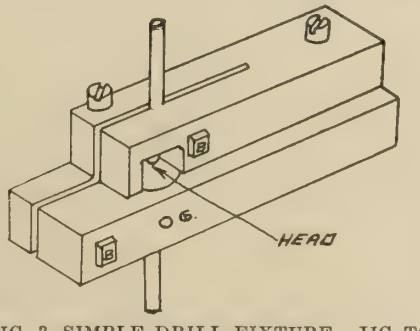

FIG. 3. SIMPLE DRILL FIXTURE. JIG TO DRILL PIN HOLE.

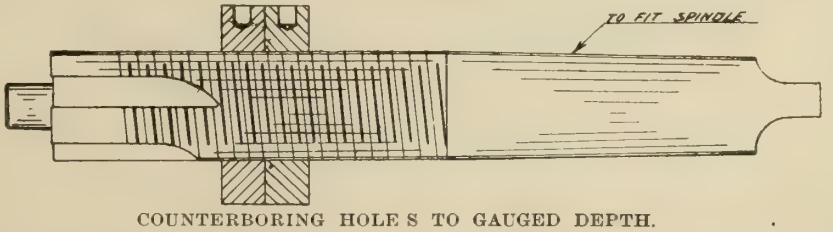
over the lower member and screwed fast. Both pieces were provided with binder screws (B) and the outfit hardened. In service, the head was inserted and clamped; then the rod was slipped through the centre hole of the head and pushed up until its projection beyond the jig was the desired amount as measured with a scale. When clamped, the jig was turned over on its side and the pin hole drilled.

The work turned out by these tools was highly satisfactory and the manufacturer owning the machine gladly paid for the jigs when their utility was explained to him. Having a post drill of his own he could then duplicate the parts himself as desired and at very little expense. That they would be accepted was in mind when the tools were made, otherwise, that for drilling the centre hole in the head would not have been constructed, for this hole could easily have been produced in the lathe When making-up only one part at a time, a dummy drilling piece of the other part was used in the jig, Fig. 3, to offset the "running" of the drill when striking the unsupported portion.

This case is a good example of the value of plain jigs for a few parts. Had no jigs been made, it would have taken at least half as long to make up the original dozen sets, using ordinary shop appliances as it did to make the tools and do the job with them. Again there was future need which the jigs would care for most economically.



COUNTERBORING HOLES TO GAUGED DEPTH.

COUNTERBORING HOLES TO A GAUGED DEPTH.

By E. W. Tate.

ILLUSTRATED herewith is a counterbore which has been successfully used in the shop where the writer is employed. It is made practically the same as the common counterbore except for a left hand thread, check and adjusting nut. It is obvious with the left hand thread, that should the nuts become loosened, the hole would be finshed to a lesser depth rather than a greater, thus preventing spoiling the piece of work.

AUTO-TRUCK OPERATION.

TO ascertain the exact cost of the operation of its motor truck, the Erie Malleable Iron Co., Erie, Pa., has devised a daily report sheet, which is filled out by the driver and covers practically every item of interest pertaining to the operation of the truck. Columns are provided for entering the time when the truck leaves the foundry and returns, and an accurate record is maintained of the weight of the material carried on each trip. Columns also are provided for the mileage covered, gasoline consumed, cost of repairs and other expenditures.

This daily report blank has enabled the company to compile interesting statistics covering the cost of operating its 1½-ton truck and the following data covers one year's operation:

Total mileage, 7,219½.
Average length of haul, 1.58 miles.
Total cost of gasoline used, $98.30.
Total cost of oil used, $55.83.
Total cost of tires, tubes, etc., $331.32.
Treads, $142.78.
Garage supplies, $25.25.
Repairs and overhauling, $28.36.
Wages, $780.
Insurance, including liability, collision and fire, $178.
Depreciation, $500.
Total cost of operation, one year, $2,114.7
Tire expense, per truck, per mile, $0.0656.
Total weight hauled, 2,449 tons.
Total cost of operation per ton mile, $0.0576.
Total cost of operation per mile, $0.2928.

PAINTING PATTERNS.

AT a joint meeting of the Steel Founders' Society and the American Society for Testing Materials, the subject of coloring patterns for steel castings was discussed and a uniform system was adopted. The finished surface is to be painted red, the rough surface yellow, and all core prints are to be painted black. The Treadwell Engineering Co., Easton, Pa., is sending to the trade a card containing a pattern in colors which clearly shows the scheme adopted by these two organizations.

A DOWNWARD MOVEMENT.

AFTER an almost continuous advance for the past twelve months, the Department of Labor's index number dropped two points in July, standing at 134.8 as compared with 136.9 in June and 126.9 in July, 1911. The chief decreases during July were in fruits and vegetables, grains and fodders, fish, animals and meats; increases being recorded in hides, leathers, boots and shoes, metals, fuel, lumber and furniture. Some 250 articles, selected to represent Canadian production and consumption, are included in the calculation by which a comparison is made of wholesale prices at the present time with the average price prevailing during the decade 1890-99.

MOTOR TRUCKS REPLACE HORSES.

WHAT seems to be the proper breadth of view regarding the superiority of motor delivery over horses is taken by A. E. Holmes, of Chicago, superintendent of a large retail furniture house. Mr. Holmes' concern replaced fifty horses with five Kissel Kar three-ton trucks, which have rendered a much cheaper as well as better service. Mr. Holmes thus expresses himself. "In our business we must be up-to-date. Our customers demand the best we can give them in service as well as in goods. Even if motor trucks were more expensive—which they are not—we would never go back to horses."

WHY MANGANESE-BRONZE CASTINGS LEAK UNDER PRESSURE.

THE extensive use of manganese bronze at the present time, and the fact that it is a strong metal, has been responsible for trouble when used for hydraulic work, high air pressure, or similar goods.

The reason that manganese bronze castings leak in this manner is because of the aluminium in them. They cannot be made, however, without the aluminium.

Aluminium, as is now well known, oxidizes when melted and wherever exposed to the air. There is always a film of oxide on the metal when it is poured, and this film becomes intermingled with the molten stream and enters the casting. So far there has been no known method of keeping it out. The result is that the casting is filled with particles of oxide of aluminium. When pressure is applied in testing the casting, these particles (they are frequently flakes, as the microscope will show) form channels, on account of not uniting with the metal, through which water, air, or other liquids or gases may pass. Hence the leakage. The remedy is to make castings to stand pressure of a good copper and tin mixture that will cast without a film of oxide and give a clean metal. This has been the universal verdict so far.—Brass World.

Boiler Tubes.—Increased efficiency and lengthened life of boiler tubes are claimed by the Topeka Edison Co., as the result of firing its boilers with fuel oil introduced from the rear of the combustion chambers. According to the Vulcan, the Topeka generating station contains four 260 horsepower, four 300 horse-power, and two 508 horsepower boilers, all equipped with rear-fired burners. A 2½-in. false floor, consisting of a single layer of firebrick, separates the combustion chamber from the air inlet ducts, each of which contains an oil burner. The heat from this partition floor helps to warm the air before it reaches the rear, and enters the furnace at the burner. Each of the smaller boilers is equipped with two air ducts and burners, and each of the 500 horsepower units with three. Oil is delivered to the fuel valves at 30 lb. per square inch pressure, while steam is taken directly from the boilers through throttling valves, reducing it to 75 lb. pressure. Each burner is made up of duplicate 10ft. lengths of ⅜-in. oil pipe and ¼-in. steam pipe, which connect the valves at the front of the boiler with the burner at the rear. Besides the steam and oil supply valves, there is a third or blow-out valve, by means of which steam can be turned in to blow all oil out of the fuel pipe when shutting down the burner.

Furnaces.—Considerable attention has been devoted on the Continent of Europe, lately, to various kinds of furnaces and appliances for burning coal-tar oil, naphthalin, etc. The production of coal-tar oil in Germany during the last five years has risen from 150,000 tons to 400,000 tons, and new uses have had to be found for it. Its application is now wide in puddling furnaces and open-hearth furnaces, and in enriching blast furnace gases where they are used for power production. It is also used in the Diesel motor. There is much to be said, however, against the use of raw coal-tar as fuel, because it contains up to 10 per cent. water, which has to be paid for, carried, and freighted as tar, and which is useless, or even harmful, in combustion. It is, further, only a raw material, and contains valuable elements which may be extracted as by-products, but which are lost when the tar is consumed as fuel. Coal-tar is not well adapted to be used as a fuel, at least in present furnaces, because it is viscous, and apt to clog the nozzles; also, notwithstanding many experiments in this direction, it cannot be used in a Diesel engine with any reliability of operation.

Brandon, Man.—Tenders addressed to Mr. Harry Brown, City Clerk, City Hall, Brandon, will be received until noon of September 27, 1912, for the delivery of two return tubular boilers and stokers. Specifications, etc., may be obtained from A. W. Shaw, engineer, Brandon.

Mr. H. E. M. Kensit, who during the past four years has been occupied in investigating and reporting on various undertakings and projects in Canada and the United States for Messrs. Smith, Kerry and Chace, of Toronto, has received an appointment with the water power branch of the Department of the Interior, Ottawa.

The Development, Use and Treatment of Alloy Tool Steel

By Frank Walker

Readers of Canadian Machinery are already familiar with the writer of this article, as a result of previously published data concerning other phases of this important requirement of our machine shops, etc. Much complimentary correspondence was received by us on former occasions, and we believe that a careful perusal of what follows will again lead to widespread satisfaction.

METALLURGICAL research of recent years has proved beyond question that the addition of small quantities of certain of the rarer metals to that combination of iron and carbon which is popularly known as "steel," imparts properties to it which increase its efficiency in the many and various uses to which it has been adoped. Steel made in this manner is known as "alloy-steel," to distinguish it from the older "carbon-steel," in which any metals or elements other than iron and carbon are present only as unavoidable impurities.

Manufacture of Alloy-Steels.

In the manufacture of alloy-steels, various metals are used, each one giving a characteristic and distinctive property to the mixture, but in all the combinations, the object aimed at is to increase the hardness and toughness of the resulting steel. The metals most generally used, and whose properties are most generally understood, are manganese nickel, chromium, tungsten, molybdenum, vanadium, and titanium. It must however, be remembered that the use of each or any of these metals does not eliminate the element of carbon, but that carbon must be present in any alloy-steel to some extent; in other words, alloy-steel is carbon-steel with a certain amount of some of the above metals added. At the same time, careful experiments and observations determine, that in order to obtain the best results, an increase in the amount of the added metals must be accompanied by a corresponding decrease,—within certain limits, in the carbon content.

The Scope of Alloy-Steel.

One of the oldest and most generally accepted uses of steel is in the manufacture of cutting tools and instruments, and in this paper, the writer proposes to deal with the use of alloy-steel as a substitute for carbon-steel in the cutting tools employed in the various processes of engineering construction, giving the approximate proportions of an alloy or mixture which will give good general service under ordinary conditions, without being too expensive, and also to endeavor to state clearly the treatments to which such an alloy must be subjected in order to obtain from it the best actual working results. It should be borne in mind that this class of steel may be obtained in short bars suitable for use in patent tool-holders; these short pieces being made in requisite sections and lengths, and fully treated, so that no other process than that of grinding is necessary to prepare them for service. This method of employing alloy-steel is much to be commended for small establishments.

Evolution of Alloy-Steel.

The evolution of a reliable alloy-steel suitable for cutting tools has entailed a large amount of chemical research and actual experiment, but the results have more than justified the labor and expense for the many advantages gained by the use of tools of this kind are now fully acknowledged by the commercial world. The principal of these advantages is their increased cutting efficiency; speeds, feeds and depths of cutting being attainable when otherwise impossible with ordinary carbon-steel tools. This characteristic has led to alloy-steel being usually described as "high-speed" steel.

Another great advantage gained by the use of high-speed tools is, that at the fast cutting speeds it is possible to adopt, a given weight of metal requires less power for its removal. In some simpler operations, this gain amounts to as much as 25 per cent. This characteristic property of alloy tool steel as compared with hardened tool steel lies in the capability to maintain hardness, notwithstanding the high temperature developed at its cutting edge by the friction of cutting. An ordinary tool steel with a carbon content of, say, from 1.0 to 1.20 per cent., however carefully it may be hardened and tempered, will commence to soften, and return to an annealed condition, if its temperature be raised above 400 deg. Fah., and the lower the temperature of a tool is maintained the longer will be the life of its cutting edge. This necessarily limits the speed at which cutting can be accomplished, but with high-speed steel a temperature of 1,000 deg. Fah., or even higher, may be produced by friction at the cutting edge without seriously affecting its hardness. It has been determined by careful experiment, that to do effective cutting, the tool should be at least three times as hard as the work, so it stands to reason that the best steel for the purpose is one that will maintain this proportion, under the conditions imposed upon it for the greatest length of time.

Constituents of Alloy Tool Steel.

The metals most generally used in making alloy tool steel are tungsten, chromium and molybdenum, and the best high-speed steels in ordinary use at the present time are combinations of iron and carbon with, (1)—tungsten and chromium: (2) — tungsten, chromium and molybdenum; (3)—chromium and molybdenum. Of these three metals, tungsten is by far the most important and is contained in almost all the principal high-speed steels; the percentage of its content having been defined by careful experiment at from 9.0 to 16.0. The chromium content has been determined in the same manner at from 2.0 to 4.0 per cent., while the advantages of molybdenum are open to question. It has been found that the addition of from 1.0 to 3.0 per cent. of molybdenum to a tungsten-chrome-steel increased its cutting efficiency, but not by such an amount as justified the cost of the added molybdenum, while, at the same time, it complicated the heat-treatment of the tool, as molybdenum alloy-steels cannot be heated above 1,800 deg. Fah., without seriously impairing their efficiency.

Reliable High-Speed Steel.

The approximate analysis of a thoroughly reliable high-speed steel is:—carbon, from .50 to .60 per cent.; tungsten .13 to .14 per cent.;chromium 3.25 to 3.75 per cent. This combination, with the presence of a slight percentage of silicon, represents, in the writer's opinion, the best alloy for cutting tools, —turning, planing, etc., used in the all round work of a general engineer's shop. With tools made from an alloy of this class, nickel-steel shafts having a carbon content of .30 have been turned at a speed of 162 feet per minute, with a cut ½ inch deep and 1-16 inch feed; the tools cutting for over six hours with one grinding, although the frictional temperature developed at the cutting-edge rose to over 1,100 deg. Fah.

Heat Treatment.

The heat-treatments of high-speed steel with the exception of that of annealing, are much more simple than those required for carbon-steel, inasmuch as accurate limitations of temperature are not so necessary, and the delicate operation of tempering is not required. If careful attention is paid to the following points,

no difficulty need be experienced in its use.

With regard to the annealing process, this entails extremely refined thermal treatment, and requires special appliances, so that it is much better that it be performed at the factory before the steel is put on the market. Buyers of this steel in the bar should insist, therefore, upon obtaining a guarantee that this process has been effected before they accept delivery. The necessity for accurately annealing this class of steel arises from the conditions under which it is made. In the process of manufacturing, the steel is cast into ingots which are drawn down under high-speed power hammers into bars of the required size and shape, this process is called "tilting," and gives rise to serious internal strains in the structure of the bar. To remove these and bring the steel to a state of molecular uniformity, and at the same time render it sufficiently soft to be machined if desired, thorough annealing is necessary.

The process is as follows:—The bars of steel are taken from the tilt to a special muffle furnace designed for heating by radiation only. In this furnace they are charged in such a manner that heat can circulate as freely as possible around each bar; care being taken that during charging, the heat of the muffle is maintained at the same temperature as that of the bars when received from the tilt. When charged, the muffle is closed and its temperature raised slowly to 1,400 deg. Fah. This temperature is most accurately maintained for from 12 to 24 hours, according to the section of the bars being treated. The fires are then allowed to die out and the muffle and its contents are allowed to gradually cool down to atmospheric temperature, the bars being afterwards withdrawn and straightened ready for service.

Heat Treatment by Toolmaker.

The heat treatments to which the steel is subjected at the hands of the toolsmith are, as remarked above, extremely simple, the main point to be observed being to break every rule usually applied to carbon-steel. This sounds paradoxical, but it is nevertheless true. The actual forging should be carried out at a bright yellow "greasy" heat—about 1900 degrees Fah., and before the piece is withdrawn from the fire it should be well "soaked" at this temperature, to insure its extending through to the core or heart of the piece. The forging should be done quickly, and if not completed before the heat falls to a bright red,—about 1500 deg. Fah., it must be returned to the fire and heated up again. The best fire to use when working high-speed steel is one made from clean gas coke.

The peculiar methods necessary with steel of this description have frequently been the cause of failure on the part of blacksmiths of the older school to give satisfaction in working it, but it must be clearly understood that an alloy-steel, with an analysis approximately as given above, cannot be spoiled by overheating short of actual fusion. A point that must be borne in mind, is, that on no account should a bar of high-speed steel be broken cold for use. If the breaking of a bar is unavoidable at any time, the broken ends should be heated and cut off some ½ inch from the fracture. The breaking of the bar cold almost always causes fine end cracks which will develop in forging and cause considerable trouble.

Hardening High-Speed Steel.

The hardening of high-speed steel is also very simple. To obtain the best results, it is only necessary to observe the following rule. This steel exhibits, as does carbon steel, that peculiar phenomenon in heating known as "the period of decalescence," and experiment has proved that the higher its temperature is raised above this critical point when reheating it for hardening, the higher will be the frictional temperature that the tool can withstand without sensibly losing its hardness. When hardening, therefore, care should be taken to raise the steel to a bright white heat,—about 2200 deg. Fah., just short of melting; in fact, no harm will be done if the extreme point of the tool be slightly fused. It should then be allowed to cool down in a brisk current of air. It is not advisable to allow the hardening heat to extend far up the tool, but it should be confined as far as possible to the cutting edges.

Grinding.

A very important operation in preparing the tool for use is that of grinding. It must be borne in mind that the largest makers of high-speed steels are also their largest and most exacting users, and their experience goes to show that no better method of grinding this class of tool can be adopted than that of the old wet grindstone, using hand pressure only. Rough grinding on dry emery-wheels before hardening has been resorted to in some cases, but the results have not proved as satisfactory as when the tool has been forged to shape on the anvil, hardened and then accurately ground on a wet sandstone by hand.

In the splendidly equipped machine shops of the Armstrong-Whitworth Co., The Cammell-Laird Co., or other large firms who combine the business of battleship building with that of steel manufacturing, one is struck by the number of wet grindstones conveniently located at different points, at each of which a skilled tool grinder is stationed to attend to the wants of the machinists. This system is also more conducive to an increased output than that of allowing the machinists, etc., to grind their own tools.—Relays of the various tools in use are kept at each grindstone, and a machinist has only to send or take his dull tools to the nearest stone, and receive from the grinder in return an equal number of similar tools sharpened ready for use.

Trade Gossip

Maisonneuve, P.Q. — A report states that the Federal Government will spend about $200,000 on the erection of a post-office in this municipality. The Minister of Public Works, Ottawa, will call tenders for the construction work.

Winnipeg, Man.—Materials for the extension of the fire service waterworks have been awarded as follows:— High pressure water pipe and specials, Canada Iron Corporation, Montreal, $64,-211.71; valves, Rensselaer Valve Co., Troy, N.Y., $3,537.50; hydrants, Florence Iron Works, Philadelphia, Pa., $11,484.

Welland, Ont. — The pumps at the new pumping station of Welland, Ont., have recently been put into service. The pumps were constructed by Messrs. Frank Pearn & Co., Ltd., Manchester, Eng., and supplied by the Canadian Boving Co., Bay street, Toronto. The water wheel is designed for the following:—Net head, 7 feet; normal output, 200 brake horse-power; maximum output, 250 brake horse-power; normal speed, 58 revolutions per minute.

The J. N. Lapointe Co., Marlboro, Mass., makers of broaching machinery, recommend the use of the following compounds when broaching steel: 2½ pounds of soda-ash; 3 gallons of mineral lard oil; and 50 gallons of water. Mix the soda-ash and the lard oil with 10 gallons of water, and add the other 40 gallons afterward.

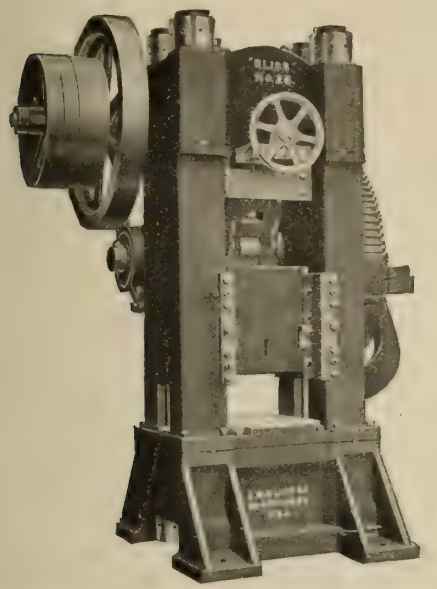
The Smart-Turner Machine Co., Ltd., of Hamilton, have recently secured the following orders:—American Radiator Co., Brantford, Ont., single acting triplex power pump; Welland House, St. Catharines, duplex pump; St. Lawrence paper mills, Mille Roches, Ont., centrifugal pump; the Nova Scotia Steel & Coal Co., Ltd., New Glasgow, N.S., one pair of rotary pumps; the Steel Castings Syndicate, Hamilton, triplex power pump; Mr. John Ritchie, Woodbridge, Ont., centrifugal pump; Berlin Brick Co., Berlin, Ont., duplex pump; the Hamilton Brewing Association, duplex pump; Dryden Timber & Power Co., Dryden, Ont., automatic feed pump and receiver.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, Blacksmith Shop or Planing Mill.

LARGE KNUCKLE JOINT PRESS.

DURING the last few years, there has been a continually increasing movement towards the building of presses of large proportions and great capacities as well as presses of new design.



Bliss No. 26 Knuckle Joint Embossing which exerts 800 tons pressure.

Every day it is demonstrated in manufacturing establishments that by means of power presses many articles can be made more economically and more uniformly than with the older methods employed. One of the new lines of knuckle joint presses recently brought out by the E. W. Bliss Co., of Brooklyn, New York, is shown in the accompanying illustration. These are designed for heavy stamping and embossing operations on steel, brass, copper, silver, britannia, etc., being particularly adapted for embossing operations in the manufacture of metals, coins, regalia, jewelry, watches, etc.

The knuckle joint principle gives with the minimum amount of friction and power a most powerful movement to the slide at the end of the stroke when the work is being done. In addition, it provides a slow movement at this point: so desirable when necessary to have the metal flow while under pressure, as in embossing. The machine is capable of exerting a pressure of 800 tons. As will be seen, the bed is stationary, and the toggle links are placed above the slide in the same position as pitmans in an ordinary crank press, being operated by a crank shaft in the rear. This construction not only allows of a longer stroke to the slide, but also permits of the use of positive knockout attachments in the bed and cross-bar knockouts in the slide, a feature appreciated by practical press men. The powerful jaw clutch with which this machine is operated, has three engaging points and is operated by a foot treadle at the right of the machine. The necessary adjustment for dies and pressure is obtained by a taper wedge adjustment. The position of this wedge is determined by means of a screw, which is operated by means of the hand wheel shown.

The machine is of tie-rod construction; the bed and crown piece each being separate castings. The side housings, which take the side strain and provide bearing surfaces for the slide and crank shaft, are also separate and of box section. Through them pass the four large vertical tie-rods which bind the machine together and take the entire strain when the press is doing its work. This method of construction not only acts as a guarantee against breaking the frame, as would be possible with a solid frame, but also provides a means of releasing the press should it become stalled on its center, as the tie-rods may be heated and expanded through suitable openings provided.

Some of the dimensions of the press shown that may be of interest, are:

Distance between uprights,28 inches.

Stroke of slide, 2 inches.

Area of slide flange, F.B. by R.L., 16 x 22 inches.

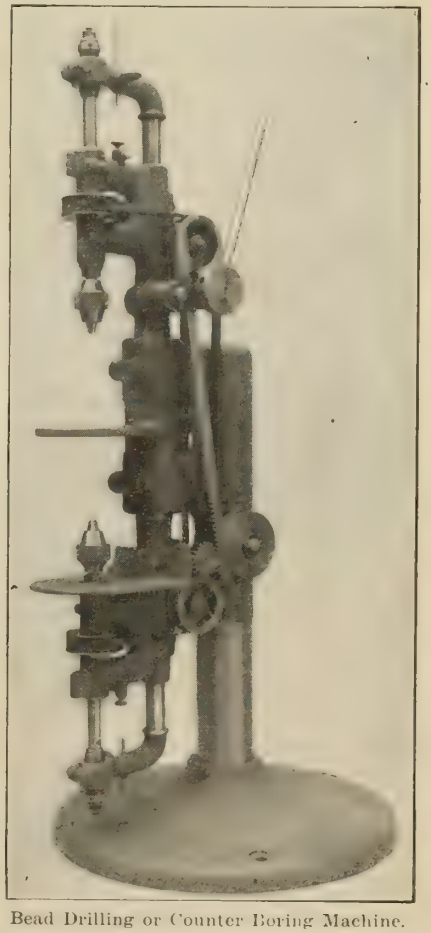
Area of top of bed, F.B. by R.L., 27 x 34 inches.

Total weight of machine, 45,000 pounds.

BEAD DRILLING OR COUNTERBORING MACHINE.

THE machine shown was designed by Langelier Mfg. Co., Providence, R. I., U.S.A., especially for counterboring the string holes in both sides of necklace and other beads. It consists essentially of a rigid column set into a wide base for attaching to the bench, supporting two sensitive drill frames so disposed that the drilling spindles work towards each other when manually operated by the lever shown, or by a foot feed passing through the bench and operated by treadle. The main driving pulleys are on opposite sides of the machine. The driving shaft extends through the column and drives both drilling spindles by means of an endless belt.

The work is mounted on a low, flat fixture, set on the top of the fixed table shown midway between the drill chucks. The top of this table is exactly central between the drill points. The table may be swung to one side if desired. The two spindles are actuated through pinions, and mesh into a connecting rack. By this means, the countersinking of both sides of the bead is kept uniform. ½ inch vertical adjustment has been provided to each spindle to obtain the proper cutting position to the trills on beads of different sizes. The accuracy can be further controlled by means of the vertical depth gauges shown passing through the frames of the machine. These gauges may be set to any required

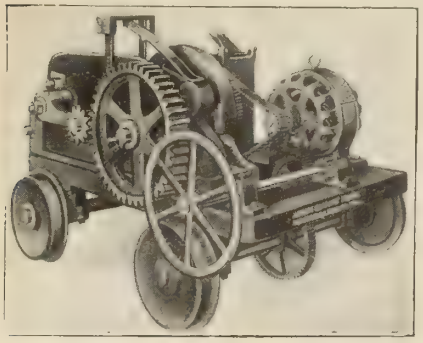


Bead Drilling or Counter Boring Machine.

distance and closely regulated by means of a knurled adjusting screw or anvil on which the tips of the gauges strike. The bench space occupied is 15 by 17 inches, and the machine weight is 114 pounds.

MOTOR OPERATED PORTABLE SHEAR.

A NOVEL motor application is shown in the accompanying illustration of a John Evans & Sons, shear mounted with its driving motor on a small flat car. The places where this machine may find a use are limited, but it is a very valuable adjunct to wholesale hardware houses, factory storehouses, railroad shops, or other places where metal bar or strap is handled. The car designed for standard gauge track and propelled by the hand wheel, is run along in front of the bins containing the material, to



Motor Operated Portable Shear.

point where the latter are cut to desired length. The shear motor is of Westinghouse make, 7½ horsepower, operating on three-phase alternating current. The current is conveyed to the motor by means of a long flexible cable, or, when used over a track of any length, a number of junction boxes for making connections to the motor is more satisfactory.

HORIZONTAL CHORD BORING MACHINE.

DESIGNED especially for use in the fabrication of the new Quebec Bridge, being built by the St. Lawrence Bridge Co., Montreal, our illustration shows a horizontal chord boring machine which is one of a number of units mounted on a long base, there installed. As a matter of convenience and economy, the long sub-base is in some instances constructed with I beams in place of the castnor base shown. The immense size of this new Quebec bridge, with its chords, pins, I bars, etc., is now so well known as to convey without special mention, the powerfulness and rigidity of equipment necessary for machining operations.

The chords, upon which the machine will operate, range up to 7 ft. 10 in. in section, and from 75 to 100 tons each. When dealing with such work, the chords are placed on parallels supported by the long sub-base, and the machine is adjusted on the base by power until the spindle is properly aligned for boring. It is then securely clamped and the table elevated against the chord to insure rigidity. On the heavy chords, the boring is accomplished by traveling head boring bars attached to the spindle sleeves by means of large diameter flanges. Feed is obtained by a pendulum arrangement, and as the webs of the chords are equidistant, about 14 or 16 inches, reversing fast power traverse to the heads is obtained in a simple and inexpensive manner, by the use of a square chuck mounted in an air drill. When boring smaller parts, the work is bolted to the elevating knee and the machine spindle feeds utilized.

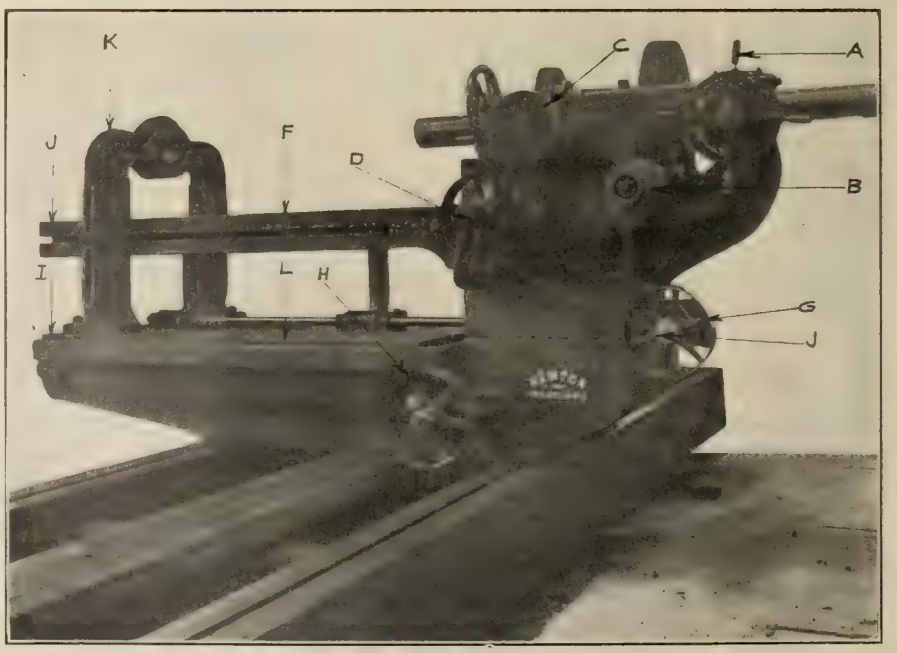
The spindle, 6 in. diameter, has 30 in. of feed with eight changes and hand control, and is fitted with a No. 7 Morse taper, with drift and retaining key slots. It is of alloy steel and fitted to the driving sleeve worm wheel by double key splines. Feed to the spindle is obtained by a steel rack fitted to the sleeve, and cuts may be started by hand by means of gear reductions, or fast traverse by hand is provided for at (A).

The Drive.

The drive is by worm and worm wheel; the worm wheel having a bronze ring with teeth of steep lead. The worm is of hardened steel and is fitted with roller thrust bearings. Both are supported in a common bearing to eliminate chatter; the horn taking the feed thrust is also cast solid. Motion for the drive is taken from a General Electric Co. motor attached to the rear of the head, either direct or through back gears to the worm shaft, on the end of which the reversible feed cone (B) is located, which in turn is belted to cone (C). Motion for rapid traverse is taken from the motor pinion to the shaft (D), which carries two loose pulleys connected by a clutch. The inner face has friction engagement for elevating the knee (F) through belt connection to pulley (G), and the outer face has a tooth clutch. The outer pulley connects by belt to pulley (H), for fast traverse of the entire unit on the sub-base.

The base of each unit is of heavy type construction and is planned on the end for attachment of extension if desired. Each base, entirely surrounded by an oil pan, is 20 inches deep and the working surface is 7 ft. 1 in. long and 48 in. wide. The knee has a finished top surface 28½ in. wide, 7 ft. 10 in. long, and has longitudinal grooves milled-in for the reception of parallels to preserve the finished surface. In addition to the power movement, the knee can be elevated by hand at positions (J) from 8½ to 28 in. from spindle centre to top table. The distance from centre of spindle to base work surface is 38½ inches.

The alignment of the elevating knee is controlled by a vertical bearing on the head and by the yoke (K). When the nature of the work demands, the knee and elevating screws can be readily removed, leaving a clear working surface on the base (L). The maximum distance from end of spindle to yoke is 74 inches, and the yoke may be adjusted to any position within this length. The machine is driven by a motor running at 500 to 1,500 r.p.m., the spindle speeds range from 7.33 to 29.33 r.p.m., and the feeds range from .014 to .085 inches. The material operated upon is steel with a large percentage of nickel.



HORIZONTAL CHORD BORING MACHINE.

AUTO HUB BORING AND REAMING OUTFIT.

THIS boring and reaming outfit does ten operations, at two "chuckings." A recent change in construction (see cut) of the Kelly Reamer, gives a more "rear" location of blades, which allows, without removal of bar side

Auto Hub Boring and Reaming Outfit.

plates, the quick exchange from boring reamer body to floating reamer, giving, as in cylinder reaming, finish and size to a "ten thousandth," and entirely eliminating "scrap hubs" through "non-fits" of ball or roller bearings.

This tool is manufactured by the Kelly Reamer Company, of Cleveland, Ohio.
